Some time ago we installed a set of 16 by 36-in. rolls. They receive a product, from a Blake crusher, varying from 2 to 2½ in. Tonnage is largely dependent on the degree of fineness to which this can be reduced by the rolls, so it is advantageous to keep them set as closely as possible. We had difficulty owing to the shells corrugating badly and causing too coarse a product from the rolls. We tried carborundum bricks for a while, but could get no satisfaction, as they became clogged with fine particles of ore and no grinding resulted.

On the suggestion of W. G. Carpenter, general superintendent, we made a frame similar to that used on a swinging cut-off circular saw and placed a mandril for an emery-stone on the bottom. This was hung on timbers above the rolls so arranged that it can be shifted laterly to cover all the shell surface and so it can be shifted to grind either the fixed or movable roll. The stone is driven from a jack-shaft hung on the same timbers as the stone and exactly over the centre of the rolls. The only change necessary is to cross the drive-belt to emery-stone when on the fixed roll. When grinding down the shells the rolls are run without feed and the emery-stone, running in the opposite direction to the shell being ground and at a speed slightly higher than the peripheral speed of the shell, is held lightly in contact with the high place desired to be ground.

Since making this installation we have had no difficulty in keeping our roll-shells fairly uniform by grinding on them two or three days in the week for about eight hours per day. We use a coarse emery-stone 2 in. wide by 12 in. diameter. The finer-grained stones are used up very quickly. As the roll-shells wore down, and to enable us to use the stones after they were worn to a small diameter, we had to cut a recess in the housing for the rolls on both sides and at each end; but this is not harmful. The last two sets of shells when removed ranged from about one-sixteenth to one-half inch in thickness.

Owing to conditions it has been necessary for some

time, when cleaning up zinc-boxes, to remove a large amount of short zinc and treat it for the recovery of bullion. It is treated by an oxidizing roast, the product being fluxed and melted in a Case tilting furnace, No. 275.

This has resulted in a large amount of slag, which contains fine prills of gold and assays rather high. Several attempts were made to treat the slag by grinding and panning, followed by amalgamation. In this way the prills were recovered, but the tailing still ran very high. A plan was considered for shipping the slag to the Selby smelter, but the cost per ton ran rather high, owing to ocean freights, several transfers, and the cost of treatment.

We took a small cast-iron cylinder, 16 in. diameter by 40 in. long, fitted with a flange and a head bolted on each end. In each head at the centre a hole was cut and threaded to receive a four-inch pipe for trunnions. This was set on a frame of six-inch timbers and two bearings made for the pipe in each end; the pipe being smoothed off to reduce friction. For the feed, a scoop was made by screwing a four-inch 90° elbow on the end of one trunnion. Into this, a four-inch nipple was screwed and on the end of the nipple another 90° elbow was screwed and riveted to the nipple to act as a shoe-and-scoop opening.

The discharge was connected to a small sluice-box, fitted with riffles and set on a slope of four inches in twelve on account of the high specific gravity of the slag. This sluice discharged into a drag-classifier made of two-inch wood, eight inches wide at the bottom and flared so as to be two feet wide at the top. The classifier was six feet long and was placed on a slope sufficient to enable the scoop to pick up the sand-discharge, thus placing the mill, sluice-box, and classifier in closed circuit. The rakes were made by taking an old chain from a bucket-chain elevator with seven-inch links. A 14-in. sprocket-wheel was placed at the head of the classifier and another one at the bottom and inside the classifier. Several links for attaching buckets were put in the chain and to these were bolted pieces of one-inch angle-iron. The sprockets were placed so that the angle-irons just cleared the back of the classifier and were dragged along the bottom to the sand-discharge. The feed was introduced near the head end of the classifier and the chain run very slowly to give the slag every opportunity to settle.

The mill was loaded with 600 lb. of soft-iron rods from 1½ to ¼ in. diameter and was driven from a slow-speed shaft by a pulley and belt around the mill at a speed of 38 revolutions.

The slag was broken by hand to minus ¾ in., and as a large proportion of it had been granulated in water, much of it was already fine enough. Most of the gold was recovered in the sluice-box as prills of fine metal. The concentrate from the box was smelted directly without further panning. Barren solution from the cyanide circuit was used in the mill and at the discharge to obtain a high dilution in the classifier. The discharge of slime, all of which was finer than 300-mesh, was run into

a 30-ft. Dorr thickener and circulated by a diaphragm-pump. Six weeks were necessary to remove all the gold by this method. If the material could have been run into an agitator, the treatment period would have been very much shortened.

The overflow of solution was run directly to a zinc-box with coco fibre in the head compartment to catch the fine slag, graphite, and fireclay held in suspension, as this material, if introduced into the precipitate, would be extremely difficult to flux.

No trouble was experienced from foul solutions or with precipitation, because the dilution of the slag was so high as to prevent the solution from going higher than \$3 per ton.

The capacity of the mill was one ton of slag in 10 hours and the consumption of power for mill and classifier was approximately 3 hp. It is obvious that there are numerous chances for improvement, such as agitating the pulp, but we had a spare thickener here and no agitator available, so it was more economical to allow the extra period in treatment and to circulate the pulp with a pump. It is advisable when grinding the slag to include the old crucibles and fireclay liners and bricks, as they assist in making the slag easier to circulate; otherwise the slag, even when very fine, has a tendency to pack and choke all the pipes. It is also wise to lock the sluice-box, unless a trustworthy man is on the mill.

The cost of erecting the mill and of materials was low and labor was cheap, so that a considerable saving was effected as compared with the cost of shipping the slag. Seventeen tons of slag in all was treated and the plant is available for treatment of similar slag in the future.

Placer Mining in Russia

The Editor:

Sir—Mining engineers will be pleased to know that our friend and colleague Mr. Leon A. Perret is safely out in Japan, now that things are so slow in Russia, and it is interesting to discuss how to operate some of these big and rich placers to best advantage so as to ensure regular and adequate dividends to capital, without which we shall not get very far.

There is no nationality from which a desire to get dividends is exempt, therefore we are really all working with the same object in view. I take it that Mr. Perret would have liked to have seen more capital (foreign or Russian) invested in mining, placer mines for preference, in Russia and Siberia, along about the time of which he writes, prior to 1917, whereas several engineers were looking for suitable properties for that purpose.

On page 415, 2nd paragraph, he says: "Few Russian undertakings can afford to develop their mines adequately previous to extraction, on account of the necessity for recovering the initial expense as quickly as possible. Want of capital, from which Russian placer mining is

suffering, accounts for the adoption of the present method". Cause and effect are obviously misplaced. It is the lack of adequate prospected reserves that causes capital to be withheld, and this is so elementary that it is not necessary to enlarge on the subject. The more frequent procedure is to prospect in the winter for the work of the coming summer. Such a hand-to-mouth policy of working in the dark is unsatisfactory and is apt to lead one accustomed to it to make the remark he does on page 392 under the caption 'Ignorance of Local Conditions', with reference to the Lenskoie company's 17-ft. dredge: "The Lenskoie company can afford to try such an experiment, but I believe there will not be many placer companies in America, to say nothing of Russia, where capital is scarce, disposed to risk such an expenditure at the start. Think of the cost of transporting two or three dredges of that size to an isolated district in Russia". Let me add as a comment: forget the cost for the moment and think of the profit in dredging ground of the "extraordinary richness and extent of the goldbearing channels of that district".

The undertaking was rendered possible by prospecting in advance sufficient ground for the life of the dredges. Proper prospecting goes a long way toward removing the business from the insinuation of the word 'experiment', which might well be applied without such prospecting. Proper prospecting results give information that can be laid on the table, and with the other data necessary helps to dispel ignorance of local conditions, and suggests suitable decisions to those putting up the money. After all, mining engineers the world over are good fellows, including Leon Perret, as I know very well, and can be convinced by the logic of facts, quicker than anyone, and this idea of his of getting around the table so hospitably provided in every issue of your paper for discussion is to be commended.

I well remember in 1912 taking up the work at Nicolo Pavda. This platinum placer ground was then apparently about worked-out; they told me on the property that years previously Mr. Perret had initiated the work with a bedrock tunnel and many of the devices described by him in the article, with excellent results at that time, before leaving for the Schuvaloff property. Had he remained, without doubt they would not have run off the lead, as happened subsequently.

However conditions altered; the ground became deeper, labor a little more costly, and the known deposit was nearly exhausted. Previous observers had considered that the boulders, clay, bedrock timbers, and difficult digging would prove unsuitable for dredging. Briefly, investigation disclosed 26,000,000 yards of good dredging ground of 32 cents per yard at that time and of double that value now. Conditions called for powerful heavy dredges, which were obtained, and success was assured from the outset. I do not believe that Mr. Perret had this property in mind when he recommended light dredges for Russia, as they would have been useless here at Kytlim. This is of no moment, however, as the Second All-Russian Congress of gold and platinum miners at Petrograd in

1915, at which I was present, decided that the industry required 200 dredges.

This illustrates the difficulty of making generalizations, for every property becomes an exception when you are about to spend money in equipping it with a view to getting maximum profits.

This particular part of the Nicolo Pavda property called for four electrically-driven elevator-dredges. One American 7½-ft. electrically-driven elevator-dredge was bought, erected, and started in 1915, working profitably from the first. The power station was three miles away in the forest—the nearest place where conditions were suitable for generating power to advantage. All the near-by forest had been cut down for previous work.

Somewhat reluctantly we installed a steam 5½-ft. dredge manufactured in Russia on easier digging ground which I had recently discovered, owing to the difficulty of getting what was wanted at that time. It was smaller and lighter than would have been selected, but we had to do the best we could. The power-plant was steam, and the boiler was good, so we got a direct comparison as far as possible under our conditions, although the work required of the steam Putiloff dredge was much easier. The American electrically-driven elevator-dredge (similar to Boyle's dredges at Dawson) was digging regularly 3000 yards and the Putiloff steam dredge just half that yardage; both worked about 17 hours per day (local Russian conditions).

The point is that the power-plant of the electric dredge consumed 3½ cubic sagenes of firewood per day whereas the steam dredge consumed 5½ cubic sagenes of similar fuel. It is incidental that the firewood cost twice as much for handling when burnt on the steam dredge, per cubic sagene, as similar fuel burnt in the power-house of the electrically-driven dredge. At Nicolo Pavda there was no divided opinion as to whether a steam or an electric dredge should be employed even before we started, but I must admit I did not realize that the difference would be so great. Subsequently two more dredges of American manufacture were purchased and there is every reason to suppose that they will give satisfactory results, as the platinum is there, and we know that this kind of machine is no experiment.

Dividends declared and paid at the end of the 1917 season amounted to 8,000,000 rubles. The stock of the company was then quoted at 450, whereas when I took charge of this work it stood at 67. Assistance was given to this result by a paper factory and sale of wood.

Working expenses of all kinds amounted to 4 cents per yard, and amortization or redemption of capital to another 4 cents per yard, on a basis of ten years life, so that there was considerable profit on 32-cents ground; and then platinum went up. The cost of working was 12 cents per yard, or three times that of the steam dredge.

There are lots of electric-power plants at factories and works in the Ural mountains using De Laval steam-turbines and jet-condensers; these have operated three or four years without delays for power, so that Mr. Perret may feel encouraged to give impartial reference to his

local conditions next time, without being prejudiced by the unforeseen difficulties encountered by the Orsk Gold-fields, as mentioned on page 395. All credit to those men who hung on for the nine long years before realizing their aim. They stayed right with it. I shall take off my hat when I meet any of them again.

This 4 cents per yard for all expenses on the property or 8 cents per yard total (at normal exchange rates) compares well with some of Mr. Perret's figures given, or rather what they were in 1915—not ten years ago. It is good, if you consider that the ground was no longer profitable under the methods of hand-work.

The old tailing-heaps at Nicolo Pavda contained no platinum worth considering, as was proved by exhaustive tests. One must certainly compliment the skilled Russian hand-washers for making a clean tailing when clay does not bother them.

That part of the ground at the Lenskoie properties which it is proposed to dredge is ground that has been abandoned as unprofitable by hand work and bedrock tunneling, the inflow of water being very large. The ground all the way to the surface, about 80 feet, contains some gold, but in less quantity, and will add materially to the yield. Neither the boulders, bedrock, sunken timbers, silt, nor clay will cause any insurmountable difficulty.

Many years ago when work was started, the shafts beside the Bodaibo river were sunk to bedrock in frozen material, but when I inspected the ground in 1916, the recent prospecting had shown that the ground to be dredged had thawed, no doubt from the effect of clearing, circulation of air, and water in the workings, and effect of the river. The surface ground could be thawed if necessary, and I hope that the time will come soon when dredges will get busy at Bodaibo. There is plenty of room on other frozen ground where the other methods so eloquently advocated and so suited to conditions still existing in that far-off gold district may have full scope.

When the Russian people again turn their attention seriously to production, the placer mines of Russia may demand and get better living conditions, possibly throwing the balance over irrevocably in favor of the use of labor-saving methods in that cold country, and it would be better to come out of the draught and investigate these methods in—well, another country in which those methods pay dividends in real money—and I among others will extend to Leon Perret the glad hand.

New York, April 8.

R. S. BOTSFORD.

IN order to secure a unified currency throughout China, the Minister of Finance and the Director of the Currency Bureau have signed an agreement with the Shanghai Mint Loan Bankers' Group for a loan of \$2,500,000, states a consular report. Shanghai Mint treasury notes to the value of \$2,500,000 will be for sale by the group, the proceeds to be employed for the establishment and equipment of the Shanghai Mint. The Government will receive \$93 for every \$100 note and the notes will bear interest at the rate of 9% per annum. There will be a monthly redemption of the principal.

Protection for the Promoter

By Sidney Norman

*In an era of paternalism that has embraced many classes in special privilege or special protection and touched others with the blight of stagnation, it is noticeable that nobody seems to have taken up the cause of the small promoter, who, with undying optimism and unflagging devotion has followed up the prospector's work with initial capital and thus aided in hewing out this glorious West for our use. As a matter of fact, the only legislation directly affecting the promoter and his calling has more or less decried his occupation, covered him with contumely, and placed him—good, bad, and indifferent—in the category of the dishonest.

There has been much discussion of the present status of the prospector and many plans have been proposed to save him from extinction. In British Columbia, from which the United States might with profit accept some suggestions, a real effort has been made to encourage his kind. Many of his problems are solved by resident Government engineers; at the present session of the legislature, \$10,000 will be appropriated to assist bona-fide prospectors in securing powder at a rate cheaper than the prevailing price. On this side of the international line, talk, and then more talk, has been the only result of the nebulous proposal.

It is my opinion that any plan for the betterment of the prospector's position must, to be successful, include consideration of the small promoter. Big capital does not engage in the initial work of developing mines; that has always been the task of the small promoter, who, in close partnership with the prospector, has provided enough capital to carry on the development work to a stage where the interest of big capital could be commanded. If the small promoter be considered in the scheme of things, it is my opinion that he must be accorded some protection from variegated, unfair, paternal, and arbitrary 'blue-sky' laws, now in effect in over thirty States of the Union.

It must be apparent that such men are essential to the development of the West. It is only the adventurous promoter, seeking independence, who will devote himself to the difficult tasks that, from small beginnings, lead to the greater development of our mining resources by big capital. Fired by unquenchable optimism, spurred by the hope of making a mine where none existed before, he has traveled the length and breadth of this land, trumpeting the opportunities of the West. He has sometimes succeeded, more often failed, but, win or lose, he has always been the most eloquent missionary and the most effective publicity agent of our mineral resources. In the last decade the efforts of both him and his partner, the prospector, have been largely circumscribed by paternalism

and over-regulation; and I am not afraid to say that a very appreciable measure of the stagnation we have suffered in the mining industry is ascribable to that fact.

It has often been pointed out to me that 'blue-sky' laws do not interfere with the big promoter, the capitalist, or the producing mine. That is undeniably so, but it is not the big promoter or capitalist to whom we owe the greater debt; that we owe to the prospector and the small promoter, who see only the rainbow in a clouded sky and go through hell on earth to reach the fabled pot of gold.

All mines were once prospects; few, if any, prospects have been converted into mines by big capital. The initial development is always left to the small promoter, who goes forth into the financial byways to collect the contributions of the many who are willing to take a chance. I wonder how far the irrepressible Jim Wardner would have proceeded under the 'blue-sky' laws of your State, for instance?

When he induced Portland capital to buy the Bunker Hill and Sullivan claims nearly thirty-five years ago, he sold a generous proportion of 'blue-sky', backed by his irresistible optimism and contagious disregard of details. The recently discovered orebody, great as it was, lay in an untracked mountain forest; it took nerve and imagination to visualize the future. But Jim Wardner did, and he was able to convey some of his enthusiasm to others.

And from his optimism, his inoculation of 'blue-sky', has grown the greatest mine of its kind in the world, which has already produced \$80,000,000 and paid over \$2,000,000 in dividends. It is equipped with a modern smelter, it employs 1200 men; the orebody gives promise of persisting several thousand feet deeper than the present lowest point, which is 1500 ft. below the Kellogg tunnel and 300 ft. below the surface. Incidentally, one of the most worthy, humane, and important industrial enterprises in the United States has been built up by the men who now direct the company's destinies.

Traced back to its inception, all this is the work of a small promoter. It is not necessary to point out to a body of mining men many specific instances in which properties, generously seasoned with 'blue-sky', have eventually 'made good'. The case of the Granby Mining, Smelting & Power Co. occurs to me as a typical case, however. At the time it was organized twenty-five years ago, the claims of the promoters as to what could be done with an orebody running less than 2% in copper called forth the scathing denials of many engineers prominent in their profession. It was quite impossible, by all the rules of precedent, they said. And yet a small promoter, at that time heavily in debt and possessing nothing but nerve and faith, accomplished the impossible to the

*An address delivered before the Third International Mining Convention, at Portland, on April 8, 1921.

benefit of the North-West and of the world. His dream has already resulted in the payment of over \$10,000,000 in dividends, the erection of two large smelters, and the expenditure in labor and supplies of certainly over \$50,000,000.

Speaking of Jim Wardner, one of the really picturesque characters of the mining West, reminds me of a story containing a good definition of 'promoter'. In the early days of the mining town of Wardner, named after him, Jim was having a particularly hard time and was completely down in the mouth. It was cold and uncomfortable in the primitive shacks that did duty for hotels in those days; and one morning, thoroughly disgusted, Jim realized that he was without a cent and very much in need of a 'bracer'. He went over a mental list of bartender's wares and decided that, above all things, he would like a real sure-enough egg-nog. With Jim, to desire a thing was to go after it. So he walked over to an acquaintance with a little more worldly wealth than he possessed and asked him if an egg-nog would not tickle his palate that particular morning.

"Sure", said the man, "but how in hell are we to get it here?"

"Tell you what I'll do," said Jim, "If you'll supply the liquor, I'll find the eggs."

"Done," said his friend, "go ahead and get your eggs."

Then Jim walked over to the leading store and said to the proprietor: "Say, Jack, how would you like an egg-nog this morning?"

"Best on earth," said Jack.

"Well," said Jim, "tell you what I'll do; if you'll furnish the eggs, I'll furnish the booze."

"You're on," replied Jack.

So off they started for a saloon, armed with three or four eggs without much pedigree. The other fellow was picked up on the way and pretty soon three fine-looking egg-nogs were pushed across the bar. As the mixologist started the last toward Jim, the man who had paid for the 'booze' grasped the situation and made a belated movement to draw the glass back, just as Jim's hand closed over it like a vise.

"Here," said he, "where do you come in, Jim?"

"I'm the promoter," snapped Jim, as he drank it down.

While in these days I would rather have the job of providing the eggs than the 'booze', I think this story defines what a promoter is. He is one who makes something out of nothing and generously shares what he makes with others.

It is understandable to me why Eastern States with no mineral resources to develop should legislate against the removal of capital to the West; but, as a matter of fact, 'blue-sky' legislation in Eastern States has not proved satisfactory. Only last year, the Iowa Bankers' Association drew attention to the serious condition which had arisen in the State through the stamp of approval placed by its law upon worthless promotions. Millions of dollars were being taken annually from the savings of the people

by dishonest men who received from the State a warrant to go forth and rob.

Nebraska's law has also been found unsatisfactory, and there was some talk of repeal during the last session of the legislature. I am not advised as to how the effort fared. So far as Western States are concerned, I cannot for the life of me understand the spirit that prompts the enactment of half-baked restrictive laws that bear with annihilatory weight upon the mining industry. Arizona, California, and your own State among others have passed such laws and I think it is the concensus of opinion that they have largely failed in their purpose of protecting the public; at the same time they have helped to destroy the spirit of venture that must be preserved if mining development is to be carried on.

The trouble with most 'blue-sky' laws is that they do not prevent failure or loss, but always act as a brake upon the initiative of the honest and energetic. Perhaps the actual experiences of a Montana friend of mine will illustrate more clearly the difficulties that now beset the small promoter's path.

He was interested in a district which had been quiescent for many years, but which was again brought to the front by the advance in the price of silver. He resurrected an old mine, and, after putting it in shape for economical operation, set out to raise \$250,000, to complete his plan of development. By the by, it might be well to say here that he eventually succeeded and added one more producing and profitable mine to Montana's long list. Before he succeeded, however, he met with much grief.

First, he went to Michigan, where a great many old friends resided, and was compelled to go before the Securities Commission, consisting of five men, including the State Bank Examiner, Secretary of State, and Attorney General. The commission sent out a representative to make an examination—in this case a young boy who had just graduated from mining college. He was absolutely unfamiliar with Western ore deposits and, in fact, had never been West before. He made a cursory examination of the mine, inquired as to the standing of my friend the promoter, and reported to the Commission that the property had merit and was worthy of a flotation price of \$250,000, which was just the net sum my friend needed. As the brokers handling the stock wished to sell it above par to provide for commissions and other expenses, the State refused to grant a license until the mine could be proved productive.

Then my friend moved on to Ohio, where all mining securities must be submitted to one man, a political appointee. Again a representative of the State was sent to examine the mine, in this case one who previous to his appointment had been in the real estate and insurance business. He 'examined' the mine, perhaps with the imagination of a real estate speculator, and recommended that a permit be issued for sale of stock in Ohio at four times par, or \$1,000,000.

Thus, by moving from Michigan to Ohio, my friend had increased the official value of his mine 400%, which

may be considered a very fair few weeks work. The experience teaches the absolute folly and impropriety of any State attempting to place valuations upon speculative property, one of the glaring mistakes of 'blue-sky' laws in general.

My friend later visited Illinois, where the same conditions were met with, and Connecticut, where 'blue-sky' protection appears to be limited to mining and oil securities. Continuing his financial search, he visited most of the States in the East, ascertaining that none of the New England States, with the exception of Connecticut, or the State of New York, Indiana, Pennsylvania, New Jersey, or Delaware, has yet been bitten with the 'blue-sky' craze. Finally, my friend opened offices in Boston and New York and conducted by mail in many States a campaign he was not permitted to make by specific laws of those States.

This points to the obvious conclusion that nothing short of a Federal law can control the mail-order stock salesman, who, to my mind, has been productive of the greatest amount of dishonesty in the promotion business. I believe those who know me best will give me credit for desire to inject all the honesty possible into the business of mine promotion. I have done what I could in my publication to discourage the crook and to help the small man who is struggling to finance a legitimate proposition. It is undeniable that the business is often disgraced by flagrant dishonesty, but in my opinion the occasions are no more frequent than in other lines. We do not have to look back far to find instances of deliberate dishonesty in the banking business, in the bond business, in the public utility business, or, in fact, any other in which some element of chance is unavoidable and in which shifting conditions may upset all calculations. And yet, we do not advocate laws to drive the banker, or the bond dealer, or the railway builder out of business.

I object most strenuously to the basic principles which underlie the average 'blue-sky' law, by which arbitrary power is built up and a political appointee given the right to say whether or not a project is worthy, or whether a promoter is honest or dishonest. No law worthy of the name 'American' should deny a man 'his day in court' under constitutional law when charged with or suspected of crime. Any law should state specifically how it may be complied with; when its provisions have been fairly met any citizen should be allowed to go about his business without let or hindrance just so long as he stays strictly and in good faith within the law. No law can be good law that sets aside constituted authority and raises up an individual with plenary power to control at will the actions of other men.

It is patent to me that if you eliminate the hope of great reward, you will also kill the spirit of venture that prompts the average man to put his luck to the touch. A fool cannot be protected from his folly short of the four square walls of a lunatic asylum, and there is no just reason why honest endeavor should be restricted in pursuit of the impossible. In any event, the criminal laws provide ample means for punishing the dishonest, and my observation has been that 'blue-sky' laws do nothing

of value in the way of protecting the credulous or ignorant.

Perhaps the wave of interference and restriction is on the ebb. At least I hope so. Both Montana and Washington have just refused to place drastic 'blue-sky' laws upon their statute-books, and possibly the time will come when other Western States will awake to the fact that the development of their natural resources is being seriously retarded by suppression of the spirit of venture, which must always be preserved unless the entire work of mining development is to be given over to the large company fortified by big capital.

So far I believe the majority of mining men who have listened to me will agree in the main with what I have said. As to methods of improving the conditions which confront the small promoter, good men differ. Unification of 'blue-sky' laws is the remedy most often suggested, and there can be no manner of doubt but that it would be the most effective way. I do not believe, however, that it could be brought about, at least not in time to benefit the present generation. Within that time the small mining promoter might become as extinct as the dodo, or his own side-partner, the prospector. I have no desire to introduce a controversial subject, but it is my impression that conditions will never be changed for the better until a Federal law supersedes all State 'blue-sky' laws. There is no greater enemy of bureaucracy than am I, but I would rather submit to one more Federal bureau of control than over thirty State bureaus that are now strangling development of Western mineral resources.

In this audience are men unalterably opposed to further governmental interference with business and, knowing the injustice and petty tyranny to which they have been subjected, especially in the conduct of big mining operations, in the past five years, I most deeply respect their opinions and do not blame them for the attitude they have assumed. It is obvious, however, that such a Federal law would not interfere with the operations of large concerns; in fact, it would only control the efforts of those who sought to raise capital in a general way from the public.

Briefly, my suggestion is that a national effort be made to secure enactment of a Federal law by which a corporation department of the Bureau of Mines be constituted the clearing-house for new mining and oil corporations seeking capital. The law should be specific, saying just what must be done to comply with it, and when its provisions have been met, and a corporation's good faith established to the satisfaction of those in charge of administering the law, a permit must issue allowing any honest man to seek capital in any State of the Union.

Compliance with the provisions of such a law could be made easy by delegating power to accept applications at the Bureau of Mines stations now in operation. Any obvious misstatement in applications could thus be checked at the source, and, in cases where it became necessary, examinations could be made to ascertain whether or not fraud was being attempted. Such a Federal law could also bring every seeker for capital under the postal laws and thus enable the Government to stamp out, once

and for all, the mail-order promoter of the get-rich-quick type, who now constitutes such a drain upon the savings of the ignorant.

In my opinion such a plan would rid the mining business of many barnacles of dishonesty, it would provide the fullest possible protection to the unwary and ignorant, and at the same time it would allow the maximum opportunity for honest men to engage in the patriotic work of developing the great mineral resources of the West.

I fully realize that such a plan as I propose involves some important legal and constitutional questions, upon which I am not fully advised. Whether or not States rights in such matters could be superseded by a Federal law I do not know, but I am advised by well-informed attorneys that they could, provided that in the opinion of Congress the matter was national in scope and could only be handled properly by Federal law. Failing that, however, I believe the same end could be gained by acquiescence of the States now carrying 'blue-sky' laws upon their statute-books. It would take time, of course, but, in my opinion, the effort would be well worth-while.

I give you this thought as one who has studied the 'blue-sky' question intensively in the last few months, and as one who has thoroughly convinced himself that the rapid elimination of the small promoter by restrictive meddlesome laws has been a serious blow to the mining industry of the West. The suggestion may be at least worthy of discussion and thought.

Handling of Explosives

The facts developed in the administration of the Explosives Act of October 6, 1917, emphasize the need for close supervision over and control of the manufacture, storage, transportation, and use of explosives in order properly to protect the people of this country from accidents occurring from them or outrages committed with them, is the conclusion reached by Charles E. Munroe in Bulletin 198, of the Bureau of Mines. As has been pointed out, this may be accomplished by the enactment of a uniform law by each of the States and by the United States to cover its Territories, the District of Columbia, and all other possessions, if such laws are uniformly administered, or, by a single Federal law operating throughout the land. The following is offered as a proposed form of peace-time legislation which if enacted into law would, when efficiently administered, go far toward securing the protection needed: For investigations of explosions and fires caused by explosives in mines, quarries, factories, warehouses, magazines, houses, cars, boats, conveyances, and all places in which explosives or the ingredients thereof are manufactured, distributed, stored, or used, with a view to recommending safe methods for the manufacture, distribution, storage, and use of explosives to the end that precautions may be taken to prevent such explosions and fires, and including personal services in the District of Columbia and elsewhere, printing and binding, supplies and equipment, traveling and subsistence expenses, maintenance,

repair, hire, and operation of motor-propelled passenger-carrying vehicles, \$35,000 or so much thereof as may be required for expenses incurred in connection with the work during the fiscal year . . . *Provided*, That the Director of the Bureau of Mines shall, in his discretion, report his findings, in such manner as he may deem fit, to the proper Federal or State authorities, to the end that if such explosion or fire has been brought about by a wilful act the person or persons causing such act may be proceeded against and brought to justice; or, if said explosion or fire has been brought about by accidental means, that precautions may be taken to prevent similar accidents from occurring.

The United States, says the bulletin, is practically the only civilized country in the world that fails to exercise a national supervision over the manufacture, storage, and use of explosives; in time of peace it is easier to obtain explosives in this country than in any other. Some of the States have no laws relative to explosives; in others, explosives may be obtained for any purpose. Large stores of explosives have been found by the Bureau of Mines within the limits of cities and towns where an explosion might have caused loss of life, limb, and property. Powder magazines are in many cases of improper construction, not proof against fire or bullets, and without guard protection. Not a few accidents to children have been attributable to the careless manner in which powder magazines are locked or secured, and to the abandoning of explosives in quarries and excavations. Occasionally, miners have taken frozen explosives home for the purpose of thawing them, and have blown up themselves and their homes. There have been instances where State convicts have used dynamite in their work on the public roads, have left it hidden, and, when their terms have expired, have recovered the explosive and used it for safe-blowing or other criminal purpose. The wholesale destruction of fish by the dynamiting of streams is a common offense. The protection of citizens and of property against bomb outrages is a matter closely connected with proper explosives regulation. Explosives are fundamental necessities of modern civilization, and their uses in industry are so varied and extensive that safe disposition and employment is a matter of importance to every citizen. For economy and efficiency in use, it is imperative that explosives should be readily accessible. As a result, they are distributed like other general merchandise, and in the absence of regulation and supervision, may be obtained by anyone. On account of the extended use of explosives during the War, thousands of persons acquired a familiarity in handling and use. With State regulation, there could be an accounting for explosives manufactured or used and means of guaranteeing safe storage. The bulletin mentioned reviews the work of the war-time regulation of explosives that was entrusted to the Bureau of Mines. In the course of the War, 16,000 agents were commissioned by the Bureau to assist in this regulation; half a million licenses for the manufacture, sale, or use of explosives were issued; ninety convictions for violations of the Federal explosives laws resulted.

Tom Reed Gold Mines v. United Eastern Company

Abstract of Decision by the Superior Court of Mohave County, Arizona

On January 1, 1904, Ely Hilty located the Grey Eagle and the Bald Eagle claims in the San Francisco mining district, at Oatman, Arizona. These locations were amended on January 10, 1909. The territory as included in these amended locations comprises a part of the estate of the Tom Reed Gold Mines Co., the plaintiff in this case. It owns this ground by virtue of a patent, dated October 31, 1917.

On September 2, 1908, the Big Jim claim was located by S. S. Jones, B. L. Lunsford, and W. L. Corbier. At the time of this location these parties were employees of the plaintiff company, and S. S. Jones had charge of the property of the plaintiff company. The location of the Big Jim claim was prior to the amended locations of the Grey Eagle and Bald Eagle claims. The locators were citizens of the United States and the territory embraced within the Big Jim location was then a part of the public domain, and no evidence was given to indicate any bad faith upon their part. On that date the ground was subject to location by them or by any other citizen.

The United Eastern Mining Co. is the owner of the Big Jim mining claim and derives its title from the Big Jim Gold Mining Co., which company secured a patent to said ground. The Tom Reed company did a very limited amount of development work on the Grey Eagle and Bald Eagle claims prior to 1916. This work on these two claims consisted principally of two shallow shafts, one of them probably ten or twelve feet deep and another about 40 ft. deep, but during that period plaintiff company was engaged in extensive mining in the district. The defendant company and its predecessor in title, the Big Jim Gold Mining Co., during the year 1915 and since have performed very extensive development work beneath the surface of the Big Jim claim. The result has been the development of an orebody valued at more than two million dollars, which orebody lies beneath the surface of the Big Jim claim.

On March 1, 1919, the plaintiff filed this suit against the defendant, to quiet title to certain portions of what it alleges to be a part of the lode belonging to the Grey Eagle and Bald Eagle claims. The case was brought to trial on November 8, 1920, before the Court without a jury, said trial being concluded on November 15, 1920. On December 1 and 2, 1920, the Court, in company with W. B. Phelps, representing the Tom Reed company, and Horace V. Winchell, representing the United Eastern company, viewed the premises in question. This view of the premises included an inspection of the various points both upon the surface and beneath the surface of these claims. On February 21, 1921, the case was presented by oral argument, at the conclusion of which it was submitted upon briefs.

The issues in this case present a suit to quiet title to an underground vein or orebody situated beneath the surface of the Big Jim claim, which claim is patented and owned by the defendant. The plaintiff owns the Grey Eagle and Bald Eagle mining claims and they are, also, patented; and said plaintiff is claiming the ore in question by its alleged extra-lateral right under what is known in mining parlance as the apex law. This law, as expressed in Section 2322 of the Revised Statutes of the United States, reads as follows:

"Locators shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes, or ledges,

throughout their entire depth, the top, or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of such surface locations."

This section gives to every mining claim, whether patented or unpatented, not only the surface within the lines of said location, but the subsurface, subject to the apex rights of the owner of some other claim whose vein may enter the subsurface on its downward dip, and, in addition to the grant of the surface and subsurface, the owner of any mining claim has the right to follow his vein, lode, or ledge on its downward dip through its side-lines. In other words, the owner of a claim who has the apex within his boundary lines may pursue said vein on its dip downward outside of the vertical side-lines of such claim. This right is given by the apex law, but said right does not include the right to run a horizontal tunnel from the owner's claim into an adjoining claim owned by another party. The owner of the apexing claims does

not have this right, even though it might be essential for him to exercise it in order to reach his vein. The theory of this rule of law is that the adjoining owner has the common-law right and title to all of the other ground within his claim, except the right of apex. The patent for a lode claim not only gives title to the surface, but to the subsurface, that is, everything under the surface except what may belong to someone else because of his apex rights.

The action of the Mallery fault is the cause of this lawsuit. A fault is merely a vein which is not mineralized. It seems that faulting results from strain which accumulates in the rocks of the earth. Two of the most important causes of this strain are the operation of temperature within the rocks and the moving of weighty material from one place to another on the surface. By these movements the ordinary balance was distributed and corrected by the flow of material from below, and thereby the balance was restored. When these strains have accumulated to a point beyond the strength of the rocks, they cause the rocks to break and slip, which breaking and slipping is what is known in geology as the faulting. The Oatman district has also been lightened by erosion. A great deal of material has been moved eastward into the Sacramento valley and westward toward the Colorado river. At some time in the past, when hot waters were percolating and circulating through the openings of the rocks, the early fault-fissures of the Oatman district were mineralized, and when these faults became mineralized they then became what are known as veins. At some time later, when strain was developed in the rocks by other causes, there was a recurrence of faulting, and at this later time the movements dislocated and passed through the older fault which had become mineralized. Because the faulting which created the Mallery fault occurred at a later time and at a time when the temperature was not high, mineralization did not take place, and, for that reason, what is known as the Mallery fault is simply a fault instead of a vein.

We have established in the Oatman district two fissure systems: the older system which was mineralized, as exemplified by the Tom Reed vein, and the later system, which is not mineralized, as exemplified by the Mallery fault.

This case is governed by the law of the apex. It is essential to determine what is meant by an apex when used as a mining term. An apex is the top or highest part of the vein. For instance, commencing anywhere upon a vein and following the line on its dip to the highest point on said vein at which vein matter is found in the fissure of that vein, you arrive at its top or apex. This top or apex forms the terminal edge of the vein. If this terminal edge reaches the surface, it is called the outcrop. However, it does not have to reach the surface in order to constitute an apex. And the apex of any given vein is all that portion of its top or terminal edge from which the vein extends downward on its dip.

The word 'apex', as used in the Federal statutes, means the highest point in the vein. An apex must be the top

or terminal edge of the vein either on the surface or the nearest point to the surface, and must be the top of the vein proper rather than the top of a spur, and it must be a point from which the vein has a dip and a strike. A vein, lode, or ledge means a more or less continuous body of mineral lying within a well-defined boundary of other rock in the mass within which it is found; in other words, the body of mineral within defined boundaries in the general mass. It is not always a straight line, neither is it uniform in dip or thickness or richness of mineral matter throughout its entire course. It may be narrower in some places than in others, or it may close up for a short distance and then be followed further on. The mining acts of Congress do not define the terms vein, lode, or ledge, but as these terms are used in the Federal statutes they are applicable to any zone or belt of mineralized rock lying within boundaries clearly separating it from the neighboring rock. It includes all deposits of mineral matter found through the mineralized zone or belt coming from the same source, impressed with the same forms, and having been created by the same process. Geologists say that it is a fissure in the earth's crust filled with mineralized matter.

The vein that traverses the Grey Eagle and Bald Eagle claims lengthwise and what the plaintiff has called the 'first segment' of the Tom Reed vein, has its apex within the surface lines of those claims. Since the first of the year 1916, the plaintiff has mined the ore from this vein to a depth of 600 ft., and at that depth the vein stops abruptly against what is known as the Mallery fault. At the bottom of the vein the ore is bent upward on the hanging wall of the fault. At a distance of about 430 ft. from the 600-ft. level of the Grey Eagle, the orebody which the defendant terms the Big Jim vein and which the plaintiff terms the 'third segment' of the Tom Reed vein, stops against the foot-wall side of the Mallery fault. The ore in this vein is bent downward. The top of this orebody is about 200 ft. beneath the surface of the Big Jim claim. There is a much smaller orebody along the foot-wall of the Mallery fault between the 200-ft. level of the Big Jim and the 600-ft. level of the Grey Eagle. Experts for the defendant term this the Sideline vein. Experts for the plaintiff term this the 'second segment' of the Tom Reed vein. It is more or less a jumbled-up mass of ore that has been dragged down from about the 200-ft. level at the time of the faulting. Part of this ore is on one side of the common side-line and part of it is on the other. In order to reach the main orebody within the Big Jim, the plaintiff would either have to travel up the Mallery fault a distance of 430 ft. from the 600-ft. level of the Grey Eagle, or cross-cut through country-rock mostly beneath the surface of the Big Jim for about the same distance.

After listening to the testimony of the geologists, and after reading and re-reading the same, the Court is of the unqualified opinion that at some time in the dim and distant past, the orebodies beneath the Tom Reed property and the orebodies beneath the United Eastern property were once connected as a part and parcel of the same

general fissure and vein system, but this Court has no information as to just how many thousands or how many millions of years have elapsed since that condition existed, but that it at some time in the past did exist seems to be the opinion of all the expert witnesses on both sides. But when the faulting occurred as the result of the formation of the Mallery fault there was not only a downward displacement of approximately 430 ft., but there was a horizontal movement, the extent of which is not known, and the best proof which could be introduced as to the size of the horizontal component would be nothing more reliable than a wild guess. For instance, there is nothing before this Court that any part of the vein along the 600-ft. level within either the Grey Eagle or Bald Eagle claims was ever attached to any part of the top of the vein as found at the 200-ft. level within the surface of the Big Jim claim. About the only testimony on this point was to the effect that the horizontal movement was greater than the downward displacement.

This case involves nothing more than a novel question of the apex mining law. During the course of the trial there was not much dispute or serious conflict between the expert witnesses on both sides. The essential facts relating to existing conditions were practically admitted. The law of the case simply calls for a construction of the Federal statute, Section 2322, under which the suit was brought.

Every man is required to keep his hands off any and everything within the surface lines of a claim belonging to another, which surface lines extend vertically downward, until he sustains the heavy burden of proof that he is working upon and following the vein which has its apex within the surface lines of his claim. This apex right only attaches to the vein of any claim when said vein may be identified on its downward course and when it is a continuation of the same vein both without and within the lines of his claim; in other words, in order to assert this right of apex the vein outside must be identified with and a continuation of the vein inside of the lines. Identity and continuity are essential to the exercise of apex rights, and after the identity and continuity of the veins have been proven, there must also exist the continuity of right, as indicated by the statutes. The mineral deposit within any lode or vein may be reduced or disappear for a short distance, but if it is found again in the same general course with the same mineral within a short distance, there is a presumption of identity, but if the mineral entirely disappears, or the walls of the fissure stop so that its identity can no longer be traced, the right to follow such a vein outside the apex owner's claim is gone. If veins are separated permanently and cannot be followed as the same vein, and if it is necessary to pass through great distances of country-rock in order to connect them, in which distances there are neither mineralized walls nor seams, such veins must be deemed separate and distinct ones and cannot be identified as one and the same. The connection between an apex and the orebody in dispute can only be made by following the continuous streaks of body of quartz or ore, or by

passing through vein-matter, and such connection cannot be made by following such material or indication as the practical miner would follow in the expectation of finding ore.

The burden of proof is always upon the apex claimant. What may constitute a sufficient discovery to warrant a location of a mining claim may be entirely insufficient to justify the locator in claiming or exercising the rights reserved by the statute. That which constitutes a discovery that will make a location valid is a very different thing from what constitutes an apex to which attaches the statutory right to invade the possession of and appropriate the property which is presumed to belong to the adjoining owner. It is the object and policy of the law to encourage the prospector and miner in their efforts to discover mineral, and, therefore, as between conflicting lode claimants, the law is liberally construed in favor of the senior location. But where one claims what *prima facie* belongs to another because of the apex in the claimant's location, a more rigid rule of construction against the claimant prevails.

This case must be decided from a practical viewpoint as the miners find conditions in the ground today, or it must be decided upon the theories and testimony of geologists in accordance with conditions as they existed many thousands or millions of years ago. If the decision be based upon the theory and testimony of the geologists, it seems to me that no mining location in the Oatman district could be secure or valid. The fundamental purpose of the apex law was to give the miner what he found. The law was passed for his benefit, a reward to him for incurring the hardships incidental to the life of the prospector. When Ely Hilty located the Tom Reed vein on January 1, 1904, could it be said, under the theory of the geologists, that he discovered the orebody beneath the Big Jim claim, taking their testimony not only as to the downward displacement of 430 ft., but as to the horizontal movement? In order for Ely Hilty to prove identity, continuity of right to the vein which he discovered on that date, he would have to travel a great distance in order to find a continuation of his vein or that part of it which was attached to his discovery before the Mallery fault occurred.

We are reliably informed by geologists that this northwest section of Arizona, including the San Francisco district, experienced at some time in the past a great upheaval and sank about six thousand feet. With this in mind, the Court is compelled to view this case from a practical standpoint and adopt the views of the practical miners, and view the conditions as they are today and as they were when the rights of all parties herein were acquired.

Continuity of right means something different from the continuity of a vein. For instance, under the apex law, the identity of a vein may be clearly proven and said vein may be shown to have such practical continuity as will comply with the law and still there would not attach to said vein that continuity of right which would entitle the apex owner to follow said vein into the claim

of an adjoining owner. For instance, suppose that when the Tom Reed vein reached the 600-ft. level of the Grey Eagle claim, instead of stopping abruptly against the Mallery fault, as it does, it spread out and extended on laterally into the subsurface of the Big Jim claim. Under the apex law no extra-lateral right attaches to a blanket vein or one that extends laterally. Again, suppose that the Tom Reed vein, instead of stopping abruptly against the Mallery fault at the 600-ft. level of the Grey Eagle claim, bent upward and extended upward along the plane of the Mallery fault. Under the apex law no extra-lateral right attaches to a vein on its upward course. The statute which grants this right says "downward course" or "course downward". "Course downward" or "downward course" means, in so far as the apex statute is concerned, going down from the apex of the vein on the dip of the vein practically within the plane of the vein toward the centre of the earth. It may be argued that such a construction is unjust and is calculated to deprive apex owners of their legal rights. It might be argued that there are many veins which have a displacement of only a very few feet and that there could be no denial of their identity and practical continuity. There is no reason for such an argument in this case, because the downward displacement is over four hundred feet, and the lateral or horizontal displacement is greater than that and probably several thousand feet. It would be an impossible task to frame a rule that would do justice in all cases. In fact, lawsuits upon most subjects are not decided by any ironclad rule. Each and every case stands upon its own merits. Again, suppose that instead of this vein system having been cut in two by the Mallery fault, that it had been cut in two by another mineralized vein. Could it be argued that when the plaintiff followed its vein down to the 600-ft. and found another vein, it could then follow that vein upward 430 ft. and connect with the detached part, even if there had been no lateral or horizontal displacement? Section 2322 of the Revised Statutes of the United States does not grant extra-lateral rights under such conditions. In that event the plaintiff would not be following its own vein, but following an entirely different vein, though at some prehistoric time this second vein was located some place else or had not been found. These geological theories lead entirely too far into the uncertain realms of speculation and doubt. The lawmakers who framed the statute used the term "course downward". The law is an incentive to the miner to go down into the bowels of the earth and search for hidden treasure. It was not intended as a technical device to furnish an excuse for acquiring, through the agency of geological speculation, property which more rightfully belongs to another.

As stated before, the three essential conditions to be established in this case are *identity*, *continuity*, and *continuity of right*. The burden of proof rests upon the plaintiff. Unless plaintiff has established by a preponderance of the testimony the existence of these three conditions regarding the orebodies found within the premises

in question, its case must fall. The plaintiff introduced a great deal of convincing testimony as to identity. Among other things it proved that the ore is abruptly cut off and exists on opposite sides of the Mallery fault, that the strike and dip of the various orebodies are similar, that the vein-filling is virtually the same, that the wall-rocks are similar, and that, on the hanging-wall side of the Mallery fault the ore is bent upward while on the foot-wall side of this fault it is bent downward. But the plaintiff did not identify the ore which is located beneath the surface of the Big Jim claims as the continuation of its vein, known as the Tom Reed vein, which stops abruptly against the Mallery fault on the 600-ft. level of the Grey Eagle and Bald Eagle claims. This identity and continuity of the Tom Reed vein within the plaintiff's ground into the ground of the defendant was not proven and could not be proven, if for no other reason than because it would be impossible to ascertain the extent of the horizontal movement at the time of the formation of the Mallery fault. When a locator locates a mining claim, his claim is limited to 1500 ft., and his apex or extra-lateral rights are also limited on that claim to the same distance. These rights may be limited to a much shorter distance.

Whatever may be the length of the owner's terminal apex is the extent of his extra-lateral rights. For example, when a vein enters the end-line of a claim and continues nearly parallel with the side-lines for a part of the length of the claim, an owner of the claim can only exercise extra-lateral rights from the end at which the vein enters to the point at which it crosses the side-line. In other words, if an owner has the terminal edge of a vein within his claim for any given number of feet, he is only entitled to the same number of feet on that vein after it extends through his side-lines into the ground of the adjoining owner. Under this rule of law, because of the horizontal movement found to have occurred in these premises, and independent of other existing conditions which affect its rights, plaintiff has failed to sustain the burden of proof as to whether or not it is entitled to extra-lateral rights for any distance whatever on the Big Jim vein located within the property of the defendant. The burden of proof was upon the plaintiff to show that the orebody constituting the Big Jim vein and located beneath the surface of the Big Jim claim, is identical with and a continuation of the vein or orebody which it worked down to the 600-ft. level, which burden of proof plaintiff has failed to sustain. The testimony of all the geologists who testified in this case shows that the continuation of the Tom Reed vein on the foot-wall side of the Mallery fault is at least over 400 ft. from where it was once connected and attached to the Tom Reed vein, and probably several thousand feet from either the Grey Eagle or Bald Eagle claims. The testimony shows that these two orebodies were once part and parcel of the same fissure or vein system and that the Big Jim vein, as found beneath the surface of the Big Jim claim, is not identical with and a continuation of the Tom Reed vein, as found beneath the surface of the Grey Eagle and Bald

Eagle claims. In order to prove the identity which the law requires, it would have to be shown that the Tom Reed vein at the 600-ft. level of the Grey Eagle and Bald Eagle claims was once attached to and formed a part of the orebody constituting the Big Jim vein, and, therefore, the Big Jim orebody was a continuation of the Tom Reed orebody. This was not proved, but the testimony merely showed that they were, at one time, a part of the same general fissure or vein system. A fault which causes a downward displacement of over 400 ft. and a horizontal component of that much displacement or a great deal more, destroys the identity and continuity of the vein and deprives the apex-owner of his continuity of right to follow that vein under such conditions into the land of an adjoining owner, and Section 2322 of the Revised Statutes of the United States grants no extra-lateral rights under such circumstances. This Court has no power to enlarge the provisions of that statute. The plaintiff in this case has not established its continuity of right under that statute, because plaintiff cannot start on the apex of the Tom Reed vein, proceed on a course downward, on the Tom Reed vein, along the dip of the Tom Reed vein, practically within the plane of the Tom Reed vein, and reach the orebody found within the Big Jim vein beneath the surface of the Big Jim claim, owned by the defendant.

The Court finds that within the premises in question there exist at this time three separate and distinct veins or orebodies, namely, the Tom Reed vein, the Sideline vein, and the Big Jim vein. These veins are permanently separated, have been so separated for many centuries, and each of them possesses an individuality of its own. The only physical connection that they ever had in past ages was that each of these veins or orebodies at some time in the distant past constituted a part of one main fissure or vein system which was disrupted by the Mallery fault. So far as the testimony in this case shows, it would be impossible for any geologist, either by positive knowledge or through the agency of geological projections to locate the actual physical continuation of the Tom Reed vein. This same condition exists as to the Big Jim vein with reference to the ore which at one time constituted the upward extension of this vein. The Tom Reed or Grey Eagle vein is wholly within the ground of the plaintiff, has its apex within the ground of the plaintiff, and is owned by the plaintiff. The Big Jim vein is wholly within the ground of the defendant, has its apex within the ground of the defendant, and is owned by the defendant. The Sideline vein is partly within the ground of the plaintiff and partly within the ground of the defendant, and a part of its apex is within the ground of the plaintiff, a part is in the ground of the defendant, and a part of its apex is bisected by the common side-line of plaintiff and defendant. This vein is secondary or accidental in character and is of minor importance in comparison with the other two veins in question. As Mr. Hershey very aptly remarked during his testimony, this orebody "lagged behind" when the Mallery fault was formed. A part of this Sideline vein is owned by plaintiff and a part of this vein is the property of the defendant.

That part of the vein which has its apex wholly within the ground of the plaintiff is the property of the plaintiff. That part of the vein which has its apex wholly within the ground of the defendant and where the apex is bisected by the common side-line, is the property of the defendant. The ore beneath the surface of the Big Jim claim cannot be reached by following the Tom Reed vein from its apex in the manner outlined and limited by Section 2322 of the Federal statutes. This section of the Federal statutes is the legal authority and criterion for the exercise of extra-lateral rights. Furthermore, commencing anywhere on the dip of the Big Jim vein, if said vein were extended upward to the surface, the apex of this vein would still be entirely within the surface lines of the Big Jim claim. There are no orebodies within either the Grey Eagle or Bald Eagle claims that may be followed within the manner outlined and limited by Section 2322 of the Federal statutes which would lead into and connect with the orebodies which constitute the Big Jim vein.

Section 2322 of the Federal Revised Statutes is the guiding star in this case. Mines are usually found in mountainous regions, in the lonely places of the earth, where the surface is rough, broken, and irregular, and the veins, lodes, and ledges found beneath the surface are frequently of the same character. The lawmakers who framed Section 2322 in the year 1872 no doubt were aware of this fact, and if they had intended to extend the law of the apex so as to provide for such contingencies as are found in this case, they could have done so, but they did not, and it is not within the province of this Court to change that statute. Under that statute the defendant would be entitled to a judgment in this case even if there had been no horizontal movement when the Mallery fault was formed, but as the Mallery faulting was accompanied by a horizontal movement, there was also created another vital reason why the plaintiff's argument cannot prevail in this case.

Suppose that this Court should adopt the view that this case should be decided from the standpoint of origin, at the time when these veins, lodes, ledges, faults, and apices were formed, would it not be just as reasonable and legal to go beyond the Mallery fault period to other times and other ages and have the geologists read the story of the rocks back to the time of creation? There were no doubt prehistoric times when the premises in question presented very different conditions from those portrayed at the time of the formation of the Mallery fault or immediately preceding that time. Furthermore, if this Court should ignore that horizontal movement and that position should be sustained by higher tribunals, the title to mining property on the hanging-wall side of the Mallery fault would be just as invalid and insecure as the title on the foot-wall side of that fault. In other words, if this case should be decided upon the theory of origin, the plaintiff would not own the Tom Reed vein as found within the Bald Eagle and Grey Eagle claims, but that property might be successfully claimed by some owner of barren ground a few thousand feet away.

LOOKING DOWN SODA BUTTE CREEK TOWARD THE PARK

Cooke City and the New World Mining District

By Lyman H. Brooks Jr.

HISTORY. The New World mining district of Montana is one of the old districts that, after lying dormant for a number of years, is again showing signs of activity. The centre is Cooke City, which is situated in Park county, four miles east of the boundary of the Yellowstone National Park.

The first prospectors came into the country about 1868, but nothing was done until Horn Miller and others arrived in 1871. They first opened up some lead-silver ore on Miller mountain; and in 1877 a small Mexican furnace was built just below Cooke City to treat the lead ores from the Shofly and Street mines. In 1883 this section of country was cut off from the Crow Indian Reservation and was opened for settlement. About this time Major G. O. Eaton bought a group of claims on Republic mountain, built a lead smelter, and started to develop the property. In 1887 the Republic Mining Co. was formed, Major Eaton selling a half-interest to Messrs. Sturges and Lane of Cheyenne, Wyoming. Reuben Rickard became manager, and N. J. Tredinnick, mine superintendent. The company operated the old smelter for eighteen months; as the Republic ores contained much zinc, it was necessary to obtain the clean lead ore from Miller mountain.

Owing to the high freight-rates, the company decided, upon the advice of Rickard, to enlarge the smelter and to build a refinery. He recommended that the lead be held and that the gold and silver bullion only be shipped. However, the necessary funds were not available, so the property was temporarily abandoned.

In 1884 the Morning Star, Bunker Hill, and Black

Warrior claims were opened up on Miller mountain. Lead and silver were the chief metals, although the Black Warrior ore was rich in gold. The ores from these properties went to both the Republic smelter and the little Mexican furnace. In 1887 a Mr. Gassett obtained control of the Black Warrior and Morning Star; he built a small lead-furnace on Miller creek below the Morning Star and did a considerable amount of development work on both properties. The Morning Star was opened up by two adits and a connecting raise. The lower adit is in about 400 ft. There is said to be good ore remaining along the raise from the lower adit to the upper; however, the workings are caved and the existence of the orebodies cannot be proved.

In 1897-98 the Daisy Mining Co. began operations on Henderson mountain. The Daisy claim consisted of approximately ten acres; along the surface a considerable amount of high-grade ore containing free gold was found. The company built a 10-stamp mill on the west side of Henderson mountain and treated a quantity of ore. Later, an adit was driven to cut the orebodies at greater depth, but only sulphide ore was found. The adit is approximately 1500 ft. long; at 1100 ft. it is said that a good body of copper ore was cut. This adit was driven from the west side of the mountain; later two others were started from the east side. They penetrated complex ore of good grade, but no free-milling ore was found. Later the property was taken over by the Western Smelting & Power Company.

In 1904, ore was discovered at Goose Lake; the Copper King Mining, Milling & Development Co. was formed.

Its property consists of four patented claims about ten miles north-east of Cooke City. The company built a road to the property, installed some machinery for sinking, sunk a shaft 60 ft. deep, and did some open-cut work. In 1906 the property was bonded to W. W. McDowell and associates of Butte. Mr. McDowell continued the sinking of the shaft and did some cross-cutting, but dropped the option in 1907. It is said that the grade of the ore continued to be good as development progressed. Mr. Frank Byrne of Cooke City is manager.

In 1905, R. I. McKay took an option on the Republic Mining Co.'s property; the Buffalo-Montana Mines Co. was formed by McKay, Z. W. Davis, and associates. The property was operated intermittently for several years with little or no success, finally going into receivership, McKay becoming receiver. During the summer of 1919, W. D. Marlow took an option on the property, O. V. Miller beginning development work at the mine. He opened up some good orebodies, and in 1920 shipped ten cars of ore. Marlow could not meet his payments, so the property reverted to the old company; Miller left, and McKay attempted to carry on operations, but after a short time he shut-down the mine.

G. B. Allison arrived in Cooke City in 1905. He built a lead smelter and a power-plant and acquired numerous claims but had no success. About this time C. R. Tuttle appeared upon the scene and spent about \$200,000; nothing came of his work either.

Cooke City has been cursed with promoters; a great deal of money has been spent in the past that, if applied intelligently, might have resulted in the opening of several mines, but nothing but old ruins remain.

At present there is only one outlet for Cooke City, through the Yellowstone National Park to Gardiner on the Northern Pacific R. R., a distance of 57 miles. All transportation is by means of motor-trucks, but on the average, one can count on the road being open for only seven or eight months during the year. Two other routes have been proposed, one up Stillwater canyon from Columbus on the Northern Pacific, and the other from Red Lodge and Bear creek by the way of Mount Maurice following Clark's fork, and thence into Cooke City. The latter is an automobile road, a survey of which was made last year. A considerable amount of work was done at the end nearest Red Lodge. It will probably be two or three years before this road is completed into Cooke City.

GEOLOGY. The geology of the district is rather complex and has never been studied in detail. In general the district may be divided into three ore-zones:

- (1) The silver-lead-zinc zone of Republic and Woody mountains.
- (2) The gold-silver-lead-zinc-copper zone of Miller mountain, and part of the Stillwater country. This zone also contains straight lead-silver ores.
- (3) The copper belt of Scotch Bonnet and Henderson mountains and the Goose Lake country.

The Republic and Woody mountains section consists of a series of quartzites, limestones, and shales, resting on a basal granite. These sediments are capped by a dark-

colored rock, probably basalt, and have been intruded by a grano-diorite. The intrusion may be seen on the east side of Republic mountain. No doubt the ores came from the same source as did this igneous intrusion and are related to it.

In the sedimentary series three limestone beds occur; the middle one, locally known as the Republic lime, is about 100 ft. thick, and the only orebodies found occur in it. This limestone is overlain by a bed of shale about 50 ft. thick. About 200 ft. below the Republic limestone is another limestone, and the third limestone occurs at the top of the sedimentary series, directly under the basalt.

The sediments have been much faulted and have a dip of about 10° to the south-west. Two series of faults are noted. The major faults strike N.20°W. and have a vertical displacement of from 80 to 90 ft.; these have

MAP OF MONTANA

been cut later by a series of fissures whose trend is easterly and westerly. Where these faults and fissures appear on the surface in the Republic limestone their presence is noted by black manganese outcrops. Complex silver-lead-zinc ore is found along the fissures at the contact of the limestone and shale.

In the Irma mines the analysis of this ore resulted as follows:

Silver, ounces per ton.....	15 to 30
Lead, per cent.....	10 to 25
Zinc, per cent.....	10 to 30

The zinc occurs mainly as marmatite; very little sphalerite has been seen. Small pockets of high-grade silver-lead ore occur also. Along the fissures the limestone has been changed to quartz; the movement evidently took place after this change occurred, the broken quartz being filled with veinlets of galena. I believe the complex ore to be mainly primary and the lead-silver ore to be secondary. Large bodies of lead-silver ore occur along the major faults in the Republic mine. The lead is chiefly in the form of cerussite and anglesite, although some galena is present. Rich pockets of this ore assayed from \$150 to \$400 per ton. In these oxidized ores no zinc was found. These orebodies are no doubt of secondary en-

richment, the faults and fissures being the avenues of circulation.

On Woody mountain the same conditions are found, the black manganese showing along the faults. No ore has been found, but the old workings do not extend down more than 25 ft. At the base of Woody mountain the Mohawk Mining Co. is sinking on a fault-plane in diorite. The fault-plane is about two feet wide and contains small stringers of galena. Native silver is visible in the specimens, the ore assaying from 150 to 280 ounces.

Miller mountain consists of limestones, shales, and slates much broken by intrusions of andesite and rhyolite whose trend is south-east and north-west. Along the contact the Shofly, Bunker Hill, Bunker Hill No. 2, Morning Star, Iceberg, and Black Warrior claims are situated. A lead-carbonate ore containing silver occurs in conjunction with the complex sulphides; but as the tunnels and shafts of the properties mentioned are all caved nothing can be seen of the underground workings, so it is not known how these ores occur. It is probable that the complex ores are found along the contact of the rhyolite, and that the sediments and the lead-silver ores occur in the limestone. On the south-west slope of Miller mountain, away from the igneous intrusions, all the ores found are clean lead-silver. They occur mainly in limestone.

On the Stillwater the country-rock is granite. The veins strike north-east and south-west. The Samson group of six claims held by N. J. Tredinnick and Harry Stinson of Cooke City have indications of gold, silver, lead, and copper. The U. S. Treasury claim controlled by F. C. Byrne of Cooke City has a vein from one to two feet wide, containing lead and silver with small amounts of copper and zinc.

The gold-silver-copper ores of Scotch Bonnet, Fisher, and Henderson mountains are found in veins in the igneous rocks. No sediments except highly metamorphosed slates are found. The igneous rocks are granite and rhyolite and are, no doubt, tongues from the big granite intrusion which makes the Granite or Saw Tooth range lying to the north and east. The copper occurs in the form of chalcopryite and bornite, a considerable amount of pyrite being present. Most of the veins strike north and south, and along the mountain tops free gold occurs; the pyrite has been oxidized to limonite and the copper has been leached and carried below. However, I do not believe that secondary enrichment has occurred to any great extent.

The Goose Lake country consists of granite, except for small dikes of dark-colored igneous rock. Throughout this section are found small veins of copper ore, but not enough work has been done on them to ascertain if they continue with depth.

At Goose Lake are the large orebodies of the Copper King Mining, Milling & Development Co. The copper occurs as chalcopryite in a large pegmatite dike whose width is from 60 to 100 ft. Samples from an open-cut on the Copper King claim are said to assay as follows: gold, \$2; silver, 2 oz.; copper, 9 to 12%; and platinum, from a trace to 1/12 oz. On the Calumet, another of the same

company's claims, an open-cut 40 ft. long gives samples that assay: gold, \$1 to \$2; silver, 1½ oz; copper, 7 to 10%.

OPERATING PROPERTIES. At present there are three properties operating in the district. All are doing development work. The Glengarry Mining Co. is developing the Scotch Bonnet group of claims, on Scotch Bonnet mountain. It has opened an orebody in the pass between Scotch Bonnet and Fisher mountains and at present is driving a tunnel to tap it at depth. The tunnel is in over 800 ft. with considerable distance yet to go. However, it is hoped to cut one or two other veins before the main orebody is reached. It is said the ore assays from \$12 to \$157 per ton, in gold, silver, and copper. F. A. Hancock is manager.

The Mohawk Mining Co. is developing the 20th Century vein at the base of Woody mountain. At present the shaft is down 59 ft.; inside of timbers it measures 6 by 4½ ft. The company has a 25-hp. Fairbanks-Morse kerosene-engine to drive an Ingersoll-Rand compressor. Ingersoll-Rand machines are used. S. G. Forgeron is manager; Lyman H. Brooks Jr. is consulting engineer.

The Irma Mines property joins that of the old Republic on the south. Development work is seen in the driving of a tunnel to cut the major faults of Republic mountain. A small fault was recently cut which yielded some good ore, but the first large fault will not be reached for some time yet. The property has nine claims; the original group consisted of four; later, five others were added.

Last season two companies were working, the Republic, which has already been mentioned, and the Western Smelting & Power Co. The latter has a large number of claims in different parts of the district and has done a considerable amount of work, including the building of a copper smelter four miles above Cooke City and a hydro-electric plant on Clark's fork. Mining operations last season consisted of driving a tunnel on the Gold Dust claim, on the east side of Henderson mountain, to cut the orebodies of the Homestake claim at depth. Operations were suspended last October and at present nothing is being done.

POSSIBILITIES OF DISTRICT. The district contains a variety of ores, and I believe the development work, properly conducted, will produce some good mines. A great deal of money has been squandered in the past by promoters and others ignorant of mining. As a result Cooke City has a black eye. Nevertheless, although the failures in the past have been many, most mining men who have visited the district recently have been favorably impressed by what they have seen. Plenty of opportunities await those who are willing to venture on a promising prospect. Abundant timber is available and power-plants could be built to use the water from a number of streams.

A CANADIAN PATENT has been granted to M. H. Caron, whose process for the treatment of manganese silver ores will be recalled, for the extraction of nickel from silicate ores. By this method the material is subjected to a preparatory reducing roast, cooled under non-oxidizing conditions, and treated by suitable solution methods.

Book Reviews

Intimate Pages of Mexican History. By Edith O'Shaughnessy. Pp. 351. George H. Doran Company, New York. For sale by 'Mining and Scientific Press'. Price, \$3.

The author is the wife of Mr. Nelson O'Shaughnessy, who was attached to the American embassy at Mexico City, first as Secretary of Legation and then as Chargé d'affaires, from 1911 to 1914. Mrs. O'Shaughnessy is a clever and observant woman; she has made the most of her opportunities to study men and events; and while in Mexico she collected a large fund of information, which her literary skill has enabled her to put into attractive form. Five years ago she issued her first book, 'A Diplomat's Wife in Mexico', which was well received, as it deserved to be. It consisted of the letters written by her to her mother and described in a delightfully personal way her own experiences during the turbulent period that followed the enforced resignation of Diaz. The present book is more ambitious; it is a history of Mexico during the last fifty years, the story being told by means of an appreciative description of the careers of the successive Presidents from Diaz to Carranza. With 'El Pomposo' she has no patience; on the other hand, Porfirio Diaz is to her "one of the greatest statesmen and empire-builders of all time". De La Barra, Francisco Madero, and Victoriano Huerta are the other heroes of this story. It is a sad story, for it is written in a vein of sympathy with Mexico and the Mexican people, who have suffered greatly since the day when Diaz was driven out of office by the insurrection instigated by Madero. General Diaz, after making a brilliant military record in the war against the French, became President in 1877 (at the age of 47) and served four years; in 1884 he was again made President, retaining his hold as the Chief of State until he abdicated and went into exile on May 25, 1911, at which time he was 81 years of age. He died in Paris on July 2, 1915.

Mrs. O'Shaughnessy admires Diaz greatly; she draws his picture in warm colors and emphasizes the splendid work he did for Mexico during his long presidency. A man of fine physical presence, "his whole bearing stamped with an indomitable will and an unflinching courage", a soldier and a statesman, was Porfirio Diaz. The keynote of his rule was "Poca política, mucha administración". He did not believe in talk; his first task was to "discourage" banditry and give peace to his country by means of martial law. "Knowing the physical and moral conformation of Mexico as no other man has ever known it, the potentialities of his people, the spirit and variety of their national qualities, he proceeded first to give them the essential gift of peace, leaving that of liberty for a more profitable moment." He endeavored to develop the natural resources of the country and to establish new industries. "He proceeded to make it not only safe, but pleasant and profitable, for foreigners to invest their brains and money in Mexico." Under his rule, the railroad system of Mexico came into existence and during his time the mining industry grew into an importance it had not enjoyed since the days of Spanish domination. Before he was expelled from office he had established the credit of Mexico on a firm foundation. In 1910 Mexican bonds were selling at a premium of 5½% on the exchanges of London and Paris, and just before the Madero revolution an arrangement was made for converting the foreign debt to a 4% security. The Diaz administration left 72,000,000 pesos in hard coin for the incoming government of Madero. Mrs. O'Shaughnessy mentions a charming characteristic of Diaz: "His treatment of his inferiors, of servants, was marked by an extreme kindness, and to those of long service he displayed a simple affection, preserving at the same time respect for his position". He loved his people; for he was of them. His father was of Spanish parentage; his mother was half Asturian and half Mixtec; so he was one-quarter Indian.

After Diaz, Madero. It is related that these two met once. Madero is reported to have stated that Mexico was now ready for a democracy and that it was time for Diaz to relinquish his power into the hands of an honest man—himself. "Señor," said Diaz, "a man must be more than honest to govern Mexico." That will serve for Madero's epitaph. He was honest, but a fool in government. "Had he been a bad man, but a clever one, with his feet on the earth and some knowledge of statecraft, according to Machiavelli, the history of Mexico would have been different. His very virtues, so multiple, so apparent, so confounding even, meant her ruin and his own, and that incompetent, short, squarish hand of his, so freely used in gesture, was the predestined instrument of catastrophe." Madero was elected by popular clamor, not by the ballot. The French Secretary of Legation believed in "la démocratie intégrale"; "he was unmoved", says Mrs. O'Shaughnessy, "by jokes concerning the famous unopened sacks of votes we had seen at the Chamber of Deputies that morning, in the Protocol office—corded, sealed, bearing naively the evidence of their origin, 'Colegio Electoral de Torreón', 'de Guadalajara', 'de Chihuahua', etc., whose numbers were to forever remain a secret. He did allow, with an unavoidable smile, that it would have been wiser to remove the bales, or at least their tickets, from the cold foreign eye". Again: "Of Madero's initial sincerity no one has ever raised a doubt. His honesty was apparent to every one who approached him; his lack of preparation for government was proven immediately he came to power." He was "rash in all his promises, indiscreet in all he said, vacillating in all his acts and passionately unreflecting in all his judgments. On the face of it, had the nation been sane, it would have been known that he was not the man to govern Mexico." But the Mexican nation was not sane; it was drunk with dreams, and hypnotized by a visionary; it was bemused by words such as 'Liberty', 'Reform', 'Justice', and 'Independence'. "These words are known to every Indian equally with 'siesta' and 'maiz'. Of their origin and attributes he has no clearer idea than we of the great First Cause. Doubtless when his corn has been trampled by soldiers in the name of 'Independencia', his wife (or wives) and daughters outraged in the name of 'Libertad', his land taken from him in the name of 'Reforma', and he himself is up against a wall looking with deer-like eyes into the muzzle of a gun in the name of 'Justicia', he has a vague though necessarily brief and profitless perception of their meaning." Madero, in Mrs. O'Shaughnessy's opinion—and that of many others—was purely destructive; he did nothing to rebuild; his sentimental anarchism simply destroyed the political structure that had become enfeebled as Diaz grew old. Madero's agrarian reforms were frustrated by his unscrupulous followers. He mistook his early popularity for national prosperity. He was a Mexican Pied Piper and he led his people into the abyss. "To the very edge he preserved his illusions." The Madero family is said to have numbered 232, and a horde of them obtained office. Of these, his uncle, Ernesto Madero, was made Secretary of the Treasury. Another was his brother Gustavo, a cynical profiteer, who remarked that "of a family of clever men the only fool was President". Madero did not know how to punish, neither did he know how to reward. This was a fatal defect in a country such as Mexico where men stand or fall upon the strength of their personal following. He had frustrated the 'científicos'; he had thwarted the reactionaries; he had intimidated the holders of property; he had aroused the malicious wit of the press. Meanwhile he failed to make good his promises to the people; he was frustrated in his dream of reforming the institution of Mexico, and became open to attack by insurrection. On June 7, 1911, he had become President; in the March following, his military genius, Pascual Orozco, announced that "he would shortly be in Mexico City and would hang Madero to the largest tree in

the Plaza Mayor". In October 1912 Felix Diaz, the nephew of the ex-President, started a revolt at Vera Cruz. Early in February 1913 the City of Mexico was in full revolution under the leadership of Felix Diaz and General Reyes. The Government forces were under the command of General Huerta. On February 15 the Senate passed a resolution demanding the resignation of President Madero and the Vice-President, Pino Suarez. Three days later Madero and Suarez surrendered and were incarcerated in the Palacio Nacional. Huerta assumed the executive power. In the night of February 22, 1913, Madero and Juarez were killed under circumstances never clearly disclosed. Then Mexico went from bad to worse. The United States refused to recognize Huerta as President and his authority thereby was gradually undermined.

The sympathies of the author are with Huerta and his people. The 'esprit militaire' of the Mexican president was entirely opposed to the 'esprit universitaire' of President Wilson. They could not understand each other. The manner of Huerta's accession to power was technically "according to the Mexican constitution, by which it must be judged", she says. "There are no doubts about its completed legality." Thus: "Madero's resignation, given three days before his death, was accepted by Lascurain, the Minister for Foreign Affairs, who became President 'ipso facto'. Lascurain appointed Huerta Minister of the Interior, and then himself resigned, whereupon the executive power passed legally into Huerta's hands. It was all according to Hoyle—in this case the Constitution of the country. President Wilson judged Huerta by the standards of the United States and refused to recognize him. Meanwhile Mr. Wilson thought that Villa "was perhaps the safest man to tie to" and Mr. Bryan pronounced that bloody ruffian an "idealist". These notions led naturally to the lifting of the embargo on the exportation of arms and ammunition from the United States into Mexico and the consequent arming of Huerta's enemies. That was on February 3, 1914. In the following April came the Tampico affair, which led to the capture of Vera Cruz by American marines. Mr. Josephus Daniels has explained that the Tampico affair was different from all other insults to our flag, notably those offered by Carranza, "in that then the purpose was to force Huerta out of Mexico". It succeeded. The old Indian was beaten. He fled from the country. In July 1915 he was arrested when about to re-enter Mexico to start a revolution. On January 13, 1916, he died at El Paso. The author quotes Mr. Dooley's description of conditions in Mexico, and it is intensely funny, but to quote it here would mar the sentiment of the book, which is sad, simply because it is sympathetic to the misfortunes of the Mexican people. It is good book for all of us to read because it gives us the point of view of the Mexicans, who, after all, are most to be considered in any adjustment of their own domestic affairs.

Mrs. O'Shaughnessy says of the Huerta tragedy: "He was an Indian from the State of Jalisco, in control of the supreme power, and he acted with his usual fidelity to type. To demand of him that he be something that he was not, of Mexico something that she is not, was quite simply to invite the most evitable political disaster of modern history." He said of Wilson: "He has not understood." Neither did Huerta understand the apostle of 'The New Freedom'. We commend the book to those desiring to understand Mexico and to those looking for intellectual pleasure in reading. T. A. R.

Cams, Elementary and Advanced. By Franklin DeRonde Furman. 229 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

This is an enlargement of the author's book on 'Elementary Cams', first published five years ago. The principal features of the earlier book were a classification and development of methods of solution of problems relating to

the most commonly used cams, together with a series of factors for base-curves in common use. The additional matter in the present volume relates mainly to the development and use of more complicated base-curves, together with comparisons of the characteristic results obtained from all base-curves. The theory developed in the text is illustrated by a number of practical problems. The book will be of service to the student of machine design and to the practical designer of machinery.

Foundry Molding Machines and Pattern Equipment. Second edition. By Edwin S. Carman. 220 pp., ill., index. Published by the author. For sale by 'Mining and Scientific Press'. Price, \$5.

The author of this book, who was recently elected president of the American Society of Mechanical Engineers, has had a large part in the development of molding machines in general, and has designed several machines himself. Consequently, he is better fitted for the task of authorship than is usually the case with the writer of a book describing mechanical devices. For not only does he thoroughly understand both the principles and the machines he is discussing, but he also realizes that most of his readers do not have any such understanding, and has therefore endeavored (successfully, we think) to explain these principles and machines so clearly that anyone in the least acquainted with foundry work can follow his treatment of the subject. The first two chapters discuss various elementary principles of molding and also the theory underlying jolt-ramming. Then come three chapters on roll-over jolt machines, segregated according to the size of the mold desired. The application of jolt machines to brass and aluminum foundries is then discussed. Then comes a chapter devoted to the plain jolt machine, following which are chapters on air-operated squeezer machines and on jolt-stripper machines. Pattern equipment, flask equipment, and machine-molded cores are next discussed, in the order named. The final chapter is devoted to the design of foundations for jolt machines. The discussion in the text is supplemented by more than 200 illustrations. The book should be in the hands of every foundryman.

Introduction to the Principles of Physical Chemistry. By Edward W. Washburn. 516 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

The original purpose of the author of this book was to present the principles of modern physical chemistry in the form of a systematic course of instruction and training. Although designed primarily for the use of classes composed of students who purpose to become professional chemists or physicists, it will serve as a suitable foundation course for any class of students who wish to obtain a usable knowledge of the subject. The book is complete, much new material having been added to bring the present edition up to date; it is well written and well edited. The author has introduced an interesting modification by supplementing the names of authorities quoted with informative footnote references of interest.

Mechanical World Electrical Pocket Book for 1921. 306 pp., ill., index. Emmott & Co., Ltd., Manchester, England. Price, 2 shillings.

The principal changes made in this useful pocket-book since the 1920 edition was published, include revision of the divisions dealing with motor-starters, transmission-cables, wiring systems, electric heating and cooking, and electric elevators. In general, it may be said that the book, while naturally not so complete as the more expensive pocket-books, nevertheless gives a great deal for the money.

REVIEW OF MINING

GOLD RELIEF BILL NOW BEFORE CONGRESS

Fletcher Hamilton, State Mineralogist of California, is in receipt of a communication from Congressman Louis T. McFadden regarding the new Gold Relief Bill introduced on April 25 as H. R. 5025 in order to conserve the gold-ore resources of the nation, which are being wasted through the continued shutting-down of the gold mines. Mr. McFadden says: "The bill provides revenue from an excise of 50c. per pennyweight of fine gold contained in manufactured articles, to be collected at the time of sale, and for a premium of 50c. per pennyweight to be paid to the producers of newly-mined gold in the United States and its possessions. The Government is fully protected under the provisions of the Bill from the presentation of other than newly-mined gold to receive the premium. The bill differs from H. R. 13201, introduced by me in the last Congress, in that the period has been lessened from five to three years, and that the Secretary of the Treasury is granted full authority to terminate entirely the provisions of the Act on three months notice in the event of a return to normal economic conditions prior to the expiration of the same. Exporters of articles containing gold have been exempted, as they were from the payment of the luxury tax, in order not to interfere with foreign competition. Revenue will be derived on all gold articles of foreign manufacture sold in this country. The industrial consumers of gold have been receiving gold at the pre-war price. They will continue to receive bullion from the Mint at the monetary price of \$20.67 per ounce, but through the payment of the excise when the manufactured article is sold they will be paying more nearly the production cost of gold and thereby lessen the subsidy which in effect they now enjoy. The premium to the producer of new gold is a compensation for the increased cost of production and cannot be construed as a subsidy. The Bill provides an equitable adjustment between the producer and the industrial consumer of gold. Extensive hearings were conducted in the last Congress on this Bill and it was reported favorably by the sub-committee of the Ways and Means Committee before adjournment. Increases in freight and power-rates have more than offset any decline in wages and materials consumed in gold mining. Because of the emergency confronting the gold-mining industry, the enactment of this Bill should be expedited."

SPRING MEETING OF THE A. S. M. E. AT CHICAGO

Industrial Chicago has many things to show mechanical engineers attending the spring meeting of the A. S. M. E. on May 23 to 26. The places which offer to entertain guests in this way are too numerous to be seen by all within the four days of the meeting, so several are scheduled for each day, so arranged, as far as possible, that the individual may suit his taste by selection daily without feeling that he is missing something he would like to see. Among the opportunities offered are: Tuesday: Sears, Roebuck & Co., handling and shipping merchandise; Mandel Brothers, package handling, coal and ash handling, connection to sub-street tunnel system; Western Electric Co., manufacture of telephone apparatus and cable for the Bell Telephone system. Wednesday: Illinois Steel Co., South Works, South Chicago,

plate-mill, rail-mill, bessemer converters, and general steel-mill equipment; Commonwealth Edison Co., modern turbine central station at Fisk street; Pennsylvania Lines terminal, freight-handling plant, in connection with which there may be visited the neighboring warehouse of Marshall Field & Co. and the U. S. Terminal building; Crane Company, manufacture of valves and fittings in cast iron, malleable iron, steel, and brass, the fabrication of pipe work. Thursday: Chicago Mill & Lumber Co., 120-in. paper-machine, manufacture of fibre, corrugated board, and paper boxes; Pullman Company, Pullman cars, passenger coaches, and freight cars; Underwriters' Laboratories, testing of appliances and devices for fire prevention. Friday: Milwaukee Railway & Light Co.'s Lakeside plant, trip by rail to Milwaukee, boilers fired with powdered coal.

COPPER SHARES SHOW DECIDED IMPROVEMENT

The attached table indicates a decided buoyancy in shares of the copper-producing companies. The low quotation for 1920 was recorded in November or December of that year. The last column indicates the advance in present quotations over the 1920 low.

	—1921—		1920 Low	Close May 3	Advance
	High	Low			
A. S. & R.	44½	34½	29½	43	13½
Anaconda	42½	33½	30	41½	11½

D. C. JACKLING ON THE COPPER INDUSTRY

A non-committal attitude with respect to the copper industry is taken by D. C. Jackling, who arrived in San Francisco from New York on May 9. Nevertheless, Mr. Jackling believes that the huge copper surplus is slowly, but gradually, being reduced, and that this reduction will become more noticeable as soon as present stocks at the refineries are cleaned up. He feels that one reason for optimism is the indication that European nations are nearing some sort of an agreement. The controlling factor in the copper situation, he said, is the foreign demand. On the other hand, from the standpoint of the producer, Mr. Jackling is pessimistic, as each day's shut-down is costing the copper companies dearly. When asked as to how soon the companies under his management were likely to resume operations, Mr. Jackling was unwilling to hazard a guess other than to say it would not be before 1922. He stated that the Utah Copper Co. undoubtedly will build a 40,000-kw. power-plant at Magna if the present rates on electric power imposed by the State Public Utilities Commission are permitted to re-

main in force. He stated that it was the policy of his organization never to duplicate facilities where an efficient service could be obtained at an equitable rate, and considering the large amount of power required, with the long assured life of the Utah Copper property, necessarily some time would be required to arrive at a definite decision as to the course the company will pursue in the power matter. On May 1, the Utah Copper Co. laid off about 150 men, and the total force on the payroll now numbers about 150.

A. S. & R. CO. PASSES DIVIDEND ON COMMON STOCK

The American Smelting & Refining Co. has passed its regular quarterly dividend of 1% on the common stock. The regular quarterly dividend of 1½% was declared on the preferred stock. This is the first time since 1904 that the company has passed its common-stock dividend. The company issued the following statement in reference to the passing of the common dividend. "Owing to the low price of metals prevailing, many mines have closed down, and those still running are operating on a greatly reduced capacity. Copper, zinc, and tin are still below pre-war levels and lead was until the present week. Costs of production, especially transportation, are considerably above the pre-war period. In March we smelted only about 25% of the tonnage per day of lead ore that we did in the last quarter of 1920. All of our zinc smelters are closed, excepting only the zinc-oxide operations at Blend."

ALASKA

Juneau.—It is officially announced that the Alaska Gold Mines Co. will discontinue mining and milling operations on June 1. Negotiations are under way looking to the conversion of the company's hydro-electric power plants for use in the manufacture of paper from wood-pulp. Mine and mill equipment will be sold.

Kennecott.—Stephen Birch, president of Kennecott Copper Co., at the annual meeting of stockholders stated that the Mother Lode Copper Mines Co., a subsidiary of the Kennecott, on May 2 paid off its entire indebtedness amounting to \$1,000,000 in 5% notes. Mr. Birch in answer to a question by one of the stockholders, as to when dividends would be resumed by Kennecott, stated that no one could accurately make a prediction in this connection. He pointed out that the Braden Copper Mines in Chile has expended thus far about \$30,000,000 in improving its property which, according to geological experts, has an estimated ore-life of about 70 years. When these improvements are completed, at about the close of the present year, the various properties of Kennecott will have a capacity for production largely in excess of 200,000,000 lb. of copper per year. The Braden mines at present are operating on a restricted basis as also are the mines in Alaska.

ARIZONA

Globe.—More than 300 Mexican employees with their baggage have been taken to Nogales, Sonora, at the expense of the Inspiration Copper Co. and Gila county. The Inspiration company has agreed to transport all Mexicans who were in its employ on January 1 of this year.—Miami Copper Co.'s cost of producing copper last year was 11.898c. per pound, including estimated Federal taxes, renewals, and repairs. Deliveries of refined copper totaled 57,563,038 lb. at 18.68c. per pound. The report says production of refined copper was 55,581,328 lb. from treatment of 1,801,958 tons of ore. Development in the lower part of the main orebody was extensive and resulted in adding about 1,500,000 tons to the previous estimate with a slight lowering of the grade. Ore-reserves as of January 1, 1921, were 10,723,419 tons of 2.26% copper, 36,000,000 tons of 1% copper, 6,000,000 tons of 2% copper.

Jerome.—At a special meeting of stockholders of the Jerome Verde Copper Co., held at Phoenix on May 5, the sale of a substantial interest to the United Verde Extension Co. was authorized. The name of the new company will be the Jerome Verde Development Co. The United Verde Extension will develop the newly acquired property through its deep workings to good advantage.

Kingman.—Several mining properties are already being developed in the recently established camp of Katherine, in the Union Pass country about 35 miles from Kingman.

At the Gold Chain property a hoist and compressor have been installed. A two-compartment shaft is now being sunk at a point 125 ft. below the tunnel-level to tap, on its dip, the vein exposed at surface. A recent sampling of wide sections of the outcrop gave an assay return of from \$5 to \$10 gold and from 2 to 15 oz. silver per ton. Development work is in direct charge of F. C. Nourse.—Shaft work is under way at the Katherine Extension mine and is being expedited by the hoisting and compressor plants that were recently installed. The area lies between the Gold Chain and Katherine estates and is on the strike of the Katherine fissure. At 200 ft. the continuation of the Katherine vein is expected.

In the Katherine mine many of the headings and cross-cuts on the four levels and in the raises between them are in ore. The tonnage at present blocked-out has an estimated value well in excess of \$300,000. At a recent meeting of the Katherine stockholders in Kingman, plans were made to finance a small mill for the reduction of the Katherine ore. It is planned to sink the shaft from the 400-ft. level to a depth of 700 feet.

A. G. Cushman, of San Francisco, and Mile Wash, of Oatman, have taken over a group of claims in the vicinity of the Katherine mine and are now erecting the buildings preliminary to development work. Similar work is also being done on the Katherine-Mohawk group of claims, recently purchased by Frank T. Torpey and other San Francisco mining men. Operations will be in charge of Albert Degenhart.

At the Oatman-Revenue property, shaft work is well advanced. Henry Johnson, formerly of Chihuahua, Mexico, is in charge.—At the Roadside mine, recently optioned to Thad M. Boggs, metallurgist, and Sherman Bagg, plans are being made for development work.

Yuma County.—The property of the New La Paz Gold Mining Co. is in Yuma county, Arizona, about 12 miles north-east of the town of Blythe, California. It comprises 15 claims, lying in Goodman Arroyo, covering an area of 1596 acres. This ground was the scene of a gold rush in 1862 and was extensively worked for the following six years by dry panning. Later dry-washing machines were introduced and work was carried on in this way until this land was taken into the Colorado River Indian Reservation, from which it has only recently been released. The east end of the property was systematically prospected and sampled by E. A. Razor in 1916. The prospecting was done by means of pits, some 74 being sunk on this portion of the property. Thirty-three samples, varying in weight from 80 to 180 lb., were run through a dry-washer and the concentrates panned. The material from the pans then dried and the coarse gold separated out and weighed. The black-sand concentrates, from which the coarse gold had been removed, were then combined and assayed. The combined value is reported as averaging \$2.50 per cubic yard. The placers are to be operated by hydraulic-mining methods; 125 miners inches of water will be pumped from wells at the old town of La Paz on the banks of the Colorado river, 4½ miles east of the point of operation. The water from the tailing will be impounded and used over again, being pumped through an auxiliary plant. In operation, the water

pumped from the La Paz wells will be used as make-up water to supply the losses. The capacity of the plant is expected to be 1500 cu. yd. per day at a cost of 45c. per cubic yard of gravel mined. The accompanying illustration shows the work on the 12-in. main, which will carry the water to the reservoir 225 ft. above the gravel deposits. O. L. Grimsley is general manager.

CALIFORNIA

Altaville.—Work of straightening and timbering the shaft at the Toll Gate mine is progressing; machinery is being installed. The shaft is to be taken down to the 200-ft. level. The ore on the 100-ft. level was cross-cut 23 ft. with no wall in sight. The mine is equipped with a two-stamp mill, plates, and concentrator.—The Triple Lode mine is situated about three-quarters of a mile west of the lode proper in a 'sulphide' area of some promise. The workings on the 250-ft. level have disclosed a number of bodies of heavy sulphide. The ore differs considerably from the ore of the lode, but it may be amenable to cyanide and therefore more cheaply treated than the lode ores. No mining is being done, but the water is being kept out, pending financing.

Calaveras County.—A rich find was reported recently in the Washington mine. The mine is one of the oldest in Calaveras county, and is near the old Calaveras mine. Workings consist of numerous shallow tunnels and shafts, said to have produced about \$300,000 years ago. Recently ore was found near the end of a 700-ft. drift, and a short stope 15 ft. high and 20 ft. long yielded \$1200 on the plates and about \$500 in concentrate. The plant consists of five 850-lb. stamps, a battery built in 1873, plates, and one of the first Wilfley tables used in California.

At the Morgan mine 30 stamps are being operated, having a capacity of 15,000 tons per month. A cross-cut in the lower levels has opened up another rich shoot in the hanging-wall country. Reserves of some \$5,000,000 are reported in the mine.—The ten-stamp mill at the Finnegan mine is ready for operation. A raise was made from the 600-ft. level to the surface for the purpose of handling the ore; it is not yet timbered or equipped for hoisting. For the present the mill will handle the ore on the dump, which will be hoisted to the mill on a tram. Ultimately the mill will be equipped with stamps, classifiers, a Hardinge mill for re-grinding, plates, and concentrators. The tailing will be impounded for later treatment by cyanide.—Twenty stamps are now dropping in the mill of the Angels Camp Deep company. The grade of ore milled is being slowly bettered, and the development work both on the 500 and the 200-ft. level is being pushed.

Grass Valley.—Approximately a thousand miners are employed in the mines of the district. Of these 450 are engaged at the Empire-Pennsylvania group, 250 at the North Star, 100 at the Idaho-Maryland, 25 at the Sultana, 25 at the Allison Ranch, and the remainder in various small properties of the district. The wage agreement between the operators and the Mine Workers Protective League expires July 1. It is reported that the company will endeavor to establish a lower scale on the ground that the cost of living has decreased.

Jackson.—The Moore Mining Co. has purchased new equipment and will re-open its mine one mile south of here. Horace G. Perry is manager.

Redding.—Plans and specifications for an aerial tramway 18,329 ft. long, have been completed by the Mountain Copper Co. operating the Hornet mine at Keswick. The tram-line is designed to deliver ore direct from the mine to the loading platform of the Southern Pacific Co., and is scheduled to go into service about November 1. The company has developed a large tonnage of pyritic ore in the Hornet property, and is shipping the product to plants on San Fran-

cisco bay for conversion into chemicals and fertilizers. The Hornet also contains deposits of low-grade copper ore, but this material will be held in reserve until the copper market warrants production.

Lawrence Gardella of Oroville, who has operated two gold dredges on Clear Creek, three miles below here, for several years, has contracted to pay the American Gold Dredging Co. \$75,000 for 310 acres of pasture land lying directly west of his own holdings. Gardella's dredges have worked up to the west line of his ground. Now that the deal has been made for the land further up the creek, his No. 1

New Pipe-Line of the La Paz Mining Co.

dredge will go into the new field, which has been thoroughly prospected. According to the agreement Gardella is to pay for the land at the rate of \$3000 per month.

COLORADO

Blackhawk.—The Silver Mountain Mining Co., drifting at 260 ft. in its main shaft in Silver gulch, is mining high-grade ore, a recent assay showing 157 oz. silver. One lot is ready for shipment to the smelter. The Midwest Mining & Milling Co. is mining ore assaying 100 to 300 oz. silver per ton on its Cyclops group.—The Gilpin Eureka will shortly resume shipments of gold ore.

Breckenridge.—The Wellington Mines Co. continues development and is adding to reserves, but will not resume treatment at its two concentrating plants until there is definite improvement in prices for zinc.—The Royal Tiger Mines Co. is nearing a depth of 300 ft. in the winze below the tunnel-level, a total depth from surface of 1000 ft. The Mineral Hill holdings of the company are to be further developed this season.—The new dredge of the Blue Valley Placer Co. is nearing the rich channel in the B. & L. placer in the Blue River valley, 2½ miles north of Breckenridge. Coarse gold has already been found in recent clean-ups.—The Tonopah Placers Co. is operating its No. 1 dredge; the old No. 2 and No. 3 boats are to be dismantled.

Cripple Creek.—The Moonlight Gold Mining Co. has re-timbered the Rittenhouse shaft, on Gold hill, to the 400-ft. level and resumed operations at the first and fourth levels, where a good grade of mill-ore is exposed.—Owen Roberts, lessee of the El Paso Gold King, the first regular producer at Cripple Creek, is again shipping. A car of mill-grade ore has been consigned to the Golden Cycle mill at Colorado Springs. The same operator is also making a success of his lease on the Strong mine at Victor. Both properties are controlled by the Lennox-Giddings interests of Colorado Springs.

The Vindicator Consolidated G. M. Co., in a letter to stockholders, advises that an option has been taken on

properties in Pinal county, Arizona. The lease and bond covers 300 acres traversed by several quartz veins, the outcrops of which show free-milling gold ore with low silver content. Recent development work at depth in the Cripple Creek mines has been encouraging.

Kokomo.—A second unit is being added to the Wilfley mill in the Ten Mile district and the plant will shortly be treating close to 100 tons of ore from the Wilfley group, where a four-foot vein of sulphide ore containing 15% lead and some gold, silver, and zinc is under development. The mill and mines are operated by C. L. Wilson, of Leadville, and associates. The Terry 'selective flotation' process is in use at the mill and is making a close saving, according to reports.—The Michigan mine near the Wilfley group is also operated by Leadville men and is shipping daily 25 tons of ore with high sulphur content consigned to a chemical works at Denver, and some smelting ore to the Arkansas Valley plant at Leadville.

Ouray.—The Gold Crown mill will handle custom ores as soon as the roads are open; the plant is now being overhauled.—The Lucky 20 Mining Co. is making ready to resume operations on its Ironton Park properties.

Silverton.—The Dives, Gold King, Shenandoah, Trilby, and other San Juan mine properties are making ready to resume production as soon as the Silverton Northern railway resumes rail service. The properties named ship to the Durango smelter. The Erma Leasing Co., operating the Silver Lake property, has a large tonnage of mill-ore ready for shipment to the Iowa-Tiger mill, and several carloads of high-grade ore awaiting shipment to the Durango smelter.

The Sunnyside M. & M. Co. shut-down its lead and zinc mines near Eureka, on May 1, awaiting increased prices for these metals. The mill is of 500-ton capacity and both mines and mill employed between 500 and 700 men. The Sunnyside mine is the largest producer of the San Juan.—Development is in progress at the Toltec mine of the U. S. Mining Corporation, on an orebody 40 ft. wide of complex gold-silver-lead-copper ore. The work is at a depth of 1400 feet.

Telluride.—The Matterhorn M. & M. Co. is mining good ore from the recently acquired Butterfly-Terrible property.—The new mill of the Valley View Leasing Co. on the San Bernardo property is operating continuously and producing two carloads of concentrate weekly.—Production from the Black Bear and Smuggler Union properties has been curtailed pending the early completion of the new Smuggler Union flotation plant.

IDAHO

Coeur d'Alene.—Machine-drills are in operation on the Lookout Mountain mine on Pine creek. Installation of power equipment was completed recently and active development work started. The drills are in use in the lower cross-cut tunnel, which has been extended 435 ft. toward the vein on the 300-ft. level. In the upper workings the Lookout vein disclosed a strong showing of lead-silver ore, in carbonate form, across a 25-ft. width, and to reach this at greater depth the present tunnel was started.

The Alhambra concentrator on Elk creek is to have its capacity increased to handle 100 tons of ore daily. The entire plant will be remodeled and the work will be completed about June 1, according to Stanley A. Easton, president. Jigs, rolls, and classifiers will be added to the flotation machines now in use. The tube-mill is being re-lined. These improvements were necessitated by the recent discovery of lead-silver ore on the Crescent group. About 14 men are employed in development work on the Alhambra and Crescent properties.

A two-cent dividend, payable June 20 to shareholders of record on June 10, was declared by the newly elected trustees

of the Marsh Consolidated Mines Co. recently. This will amount to approximately \$40,000 and will leave in the neighborhood of \$50,000 in the company treasury for development work.—It is reported that lessees at the Hunter mine are finding large pockets of high-grade silver ore in the old workings of the mine. Several carloads have been shipped from these leases with satisfactory results.

Hailey.—The Bunker Hill & Sullivan company has acquired the Mayflower-Bullion mine, consisting of six claims, situated seven miles from here, and will commence operations within a short time. The Mayflower mine was originally owned by Col. E. A. Wall, of Salt Lake City, and the Bullion property was among the holdings of the Wood River Gold & Silver Mining Co. The two properties were operated in 1881, and since that time have produced over 12,000 tons of lead-silver ore with a gross value of \$2,000,000. Material and equipment have been shipped to the property. At present the Wood River Power Co. is building a power-line from Hailey to the Mayflower-Bullion, seven miles. The ore from the property will be shipped to Kellogg for treatment at the Bunker Hill smelter.

Leonla.—The plan of placer-mining at the Gold & Ruby property is unusual, according to Stewart Campbell, State Mine Inspector for Idaho. A method of separating black and gray sands has been developed, and if the new concentrating plant works as successfully on a large scale as it does in the working model, it will be a new step in placer-mining practice. It is planned to save lead, copper, and other minerals, including garnets, miscalled rubies, as well as gold.

MICHIGAN

Houghton.—The first shipment of copper by boat for the season left Houghton the last week in April. It consisted of 300,000 lb. of Calumet & Hecla copper, loaded at the company's smelter at Hubbell, for domestic consumers in the East. Within a few days 1,200,000 lb. of Calumet & Hecla copper for Germany will leave here by boat. On May 15 a similar shipment will go forward, which will clean up all German business at present on the books, amounting to a total of 4,000,000 lb. The company continues to sell considerable copper for domestic use. An order for 800,000 lb., for an Illinois customer, has just been filled. Domestic consumers are evincing more interest in the market, apparently realizing that the days of cheap copper are numbered. The Quincy Mining Co. has had a good customer in the Dollar Bay wire mill in this district, which has taken as high as a million pounds of Quincy copper per month. Quincy now is working only one furnace, part capacity, so recent sales have helped reduce the company's metal surplus.

Mohawk and Wolverine wages are back on a pre-war basis, but all other costs continue abnormally high. There has been no decrease in freight-rates, which add greatly to the expense of transporting ore and coal; coal is more than 100% higher than before the War, costing \$7.50 per ton here in cars, as compared with the previous price of \$3; powder is still high, and drill-steel is only 2c. per pound cheaper than the highest price paid during the War.

But little timbering is being done in the Calumet & Hecla shafts. Some timbering is necessary in the Red Jacket shaft, which is in use a part of each day. No. 5 shaft, Tamarack, also is being kept in repair, for this shaft is used for bailing purposes. No. 3, Tamarack, is in commission for pumping. Four machines are being used in development work on the Kearsarge lode, encountered in the east cross-cut from the 81st level of the Red Jacket shaft, and the 'rock' taken out is being brought to the haulage way and hoisted to surface.

The Victoria mine in Ontonagon county has shut-down to await a more favorable turn in the metal market. Only 70 men have been employed of late, and in the last few weeks

they have been engaged in cleaning the stopes of ore accumulated in mining operations. Victoria closed the year 1920 with a surplus of 1,180,955 lb. of copper, valued in the annual report at \$162,544 or better than 13½c. per pound.

Ground on a par with that in the other levels is being opened in the new drifts on the 6th level of the Seneca property. Drifting north is under way on the 3rd and 5th levels. All of these openings are in ground of good quality. Stopping is still being done on the 4th level and the character of the 'rock' being opened is encouraging. Drifting on this level has been stopped temporarily until stopping is completed. Seneca has made another slight reduction in wages.

MONTANA

Basin.—Two feet of high-grade silver ore has been opened in the Obelisk mine near here, according to reports reaching Butte. A sample of the ore taken across a width of 26 in. assayed 92 oz. in silver and 10% lead. The ore was struck in a raise from the 200 east drift below the tunnel-level.

Butte.—The Butte & Superior company's No. 3 shaft has reached a point within 50 ft. of the 2700-ft. level. The objective is 3000 ft. The shaft is in the south branch of the Rainbow lode; samples range from 10 to 25% zinc and from 5 to 12 oz. silver. It is reported that a drift on the 2050-ft. level disclosed 12 ft. of medium-grade chalcopryite ore. If the facts are as stated, this is the first deposit of copper ore of any consequence yet discovered in the mine.

Millon.—According to Henry Auerbach, president of the Silver Spring Mining Co., whose property is 21 miles south of here, a large tonnage of 5% lead ore has been developed. L. D. Lyons is in charge of the property. A 100-ton mill may be built.

Elkhorn.—A report states that ore assaying 1200 oz. silver per ton has been uncovered in the Union mine.

Helena.—Rich ore near the surface is being mined from the Willard mine in the Warm Springs district by the Jefferson & Teton Mining Co.

Libby.—William Criderman, William Cady, and Joe Sheffield are developing a group of claims on Libby creek 23 miles from here. They believe that they have the vein from which the gold in the productive Libby Creek placers was derived.

Lump Gulch.—A shaft is being sunk on the Pay Back property, where some excellent ore has been found on the surface.

Neihart.—Installation of new machinery at the Hartley property marks a new era for that concern. The company is employing 65 men. Work is to be started at once in the shaft, which will be sunk an additional 100 ft. to the 400-ft. level. With the output from the new level, the Hartley will ship at least 15 carloads per month. —Liscomb and Parmenter are leasing in the Florence from which they make regular shipments. —Walker and Fredson are working the Queen of the Hills and have a rich shipment ready to load.

—Haggerty and Farrell are making a shipment from the Beaver lode of the Galt. —Merzner, Graves and Brown, Martin and Watzhoff, Sheldon and Kunsumen, and Doyle and Worthington are each shipping a carload of ore from the Neihart Silver Mines property.

Dan Foote and Ed Fossum, who recently obtained a lease on a claim on the north side of old Baldy, owned by George Nelson, are reported to have found a vein five inches in width which assays \$1000 per ton. —Jack and George Powers are opening up the Lizzie, near the Silver Belt. —There are now four sets of workers leasing at the famous Big Seven mine of the Barkers. Glover and Johnson, who are at the Big Seven, will soon make a shipment.

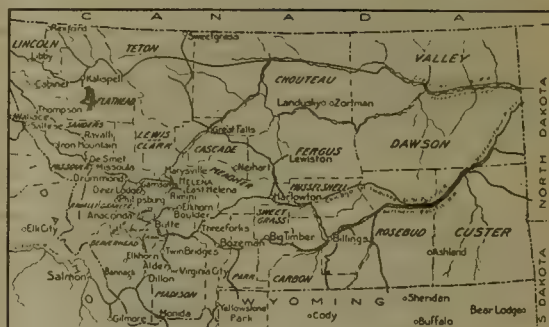

NEVADA

Ely.—The Nevada Consolidated recently fired seven 6-in.

100-ft. holes loaded with two tons of black powder and one-quarter ton of dynamite. The holes were drilled over a surface 230 by 70 ft. Another blast in which an equal quantity of powder will be used will be fired in a short time. This work is being done to consume the powder on hand.

Goldfield.—Consolidated lessees during April shipped seven carloads of ore of medium grade. An important find has been made by Simpson, Grimm, and McIntee 30 ft. below the surface at a point 300 ft. north-west of the Combination shaft. They are working in a seam of high-grade ore that is thought to be in the top of the old stopes. They have saved 35 tons of ore assaying more than \$100 and there is enough ore in sight to make a 50-ton shipment of this grade. Poffinberger and Dunn shipped three carloads last month from near the Combination shaft and they are still in ore. One carload was shipped from the Miller lease on the January vein, near the surface. Marcotte and Petrucci, on the fourth level of the Mohawk, shipped two carloads and are still in ore. The number of lessees continues to increase and the success of Simpson, Grimm, and McIntee has encouraged the holders of the various blocks.

Grantsville.—Elmer M. Bray and Jay A. Carpenter have taken a three-year lease on the Alexander or Webster mine

Map of Montana

and have started remodeling the cyanide plant to treat 40 tons of ore daily. The Alexander mine supplied ore for a 40-stamp mill for several years in the '70s and '80s, yielding \$2,000,000 in silver bullion. The ore was crushed dry in the batteries, given a chloridizing roast, and then amalgamated. At water-level the ore became a base lead, zinc, and iron sulphide ore and with the steady drop in the price of silver, the mine was abandoned in 1890.

Pioche.—The first ore-bed found by drilling has been passed through by the Pioche shaft. This bed contains low-grade ore and the shaft, now more than 700 ft. deep, is being continued to the second bed, which is richer. This second bed will be reached in 100 to 150 feet.

Rawhide.—Owners and lessees who have been in Rawhide since the 'boom' days 12 years ago, George Trost, Giles Hard, Joseph Feretta, Adolph Miller, Joseph Kelly, H. L. Spencer, John Curley, John Haines, and others, now see an opportunity to make money from low-grade ore when the mill is built by the California-Nevada Milling Co. The Western Machinery & Engineering Co., of Reno, has the contract for building the mill, and machinery is being hauled from Fallon by 12-horse teams. The capacity of the plant will be 25 to 50 tons daily, according to the grade of ore treated, and the milling charge will be \$8.50 to \$20 per ton. At present \$60 material is not ore because of the costly 45-mile haul to Fallon and the high railroad freight-charge, together with high treatment cost at the smelters. Trost has in sight 500 tons of medium-grade ore in the Grutt Morning Star Fraction. Thomas Wilson, working 1½ miles

from the Black Eagle, has stripped for 120 ft. a vein of rich ore that is 2 ft. wide. He has sunk a 40-ft. shaft on the vein and is now drifting. About 25 tons of ore in a dump at this shaft averages \$112.

Rochester.—A wage cut of 50c. from the former Tonopah scale has resulted in a strike of the 115 men employed by the Rochester Silver Mines Corporation and the mine and mill are closed. The Nevada Packard also has announced a reduction of 50c. from the former Tonopah scale. The Packard mine and mill will be started soon, with two shifts, and 125 to 150 tons will be handled daily.

Sweetwater.—A mill and cyanide plant, with a capacity of 150 tons, is planned for the Silverado mine. For two years the property has been undergoing development, and, according to A. G. Anderson of Chicago, president of the Nevada Progressive Mining Co., which owns the property, the construction of a mill is justified. E. F. Hall will superintend the work.

Tonopah.—Frank W. Ingram, State Labor Commissioner, is at Tonopah reviewing the labor situation, in which there has been no change. It is thought that, although Ingram is not at Tonopah to mediate, his visit will have a good effect and he may be able to bring the opposing factions closer together than they are at present. The present attitude of the operators is that they will make no concessions. The history of the causes leading to the present trouble in Tonopah dates from August 17, 1919, when the men struck for a \$1 increase in wages. On October 3 they returned to work without an increase in wages. This trouble was finally settled on November 7, when the operators granted a 50c. bonus in wages and other concessions. It was agreed that when it had been shown to the satisfaction of a Federal mediator that a store to be started by the operators was giving a saving of 50c. per day in living costs the 50c. bonus should be eliminated. February 8, 1920, after the mediator had reported that this saving was being provided by the store, the bonus was withdrawn, according to agreement, and a strike followed. This strike resulted in a 50c. wage increase being granted. This increase had the effect of making permanent the sum paid under the bonus system. In addition to this the operators agreed to continue the commissary. The new scale was \$6 for machine-men and \$5.50 for shovelers, trammers, and topmen. It is the removal of this 50c. increase and an additional 25c. that is the cause of the present strike. It is pointed out by the operators that, even under the new scale, wages would be equal to or higher at Tonopah than in other Nevada districts or districts in other States, and that the scale is only 25c. under what it would have been had the miners abided by the agreement of November 7. It is said that the mines have been making little profit, even with \$1 silver, and that they are being exhausted with inadequate profit to the owners and little revenue to the State. The hoisting-engineers and mechanics will be proportionately harder hit by the new scale than the other workers and it is reported that they are the only ones now standing in the way of a settlement almost completely on the terms of the operators.

Tule Canyon.—The Silver Hills mill started May 10 treating 30 tons every 16 hours. Three shifts are employed. The drift on the bottom level continues in low-grade material that is not ore.

Virginia City.—Walter Reid, metallurgist for the United Comstock, is at Virginia City completing plans for the cyaniding part of the 1000-ton mill to be built by the company. Plans for the other parts have been finished and it is expected that the flow-sheet will be completed in a short time. The Overland group and 10-stamp mill has been taken over by the Comstock Silver.

NEW MEXICO

Hurley.—Improved recovery at the mill of the Chino

Copper Co. is recorded in the annual report for 1920. During the year 70.67% of the copper in the ore was recovered; this is an increase of 5% over 1919, and still better results are expected from improvements now being made.

UTAH

Eureka.—The recent strike on the 925-ft. level at the Eureka Bullion mine is the most important development in the history of the company. A shipment of 40 tons has been made, which averaged \$2.40 in gold, 60 oz. in silver, and 2.5% lead. The place from which the ore is being taken is about 112 ft. from the winze sunk from the 800-ft. level, according to John Bestlemeyer, manager. Two headings are being driven for the development of the ore, which comes in a northeast-southwest break. Ore is showing in both headings, for a width of four or five feet.

Shipments from this district for the week ending April 30 totaled 126 cars, an increase of 6 over the previous week. The Tintic Standard shipped 47; Chief Consolidated, 34; Iron King, 17; Dragon, 9; Iron Blossom, 8; Alaska, 3; Eagle & Blue Bell, 3; Swansea, 2; Mammoth, 1; Colorado, 1; Victoria, 1.

Work of installing a compressor at the Tintic Standard property has been completed. This is one of the largest compressors in the State, having a capacity of 2750 cu. ft. of air per minute; it is situated at the No. 2 shaft. When the transformers are received and installed, the management plans to begin No. 3 shaft, as the two present shafts are unable properly to handle the tonnage of ore and waste from the mine.

Frisco.—Regular shipments are being made from the Quad-Metals mine in this district, according to Grant Snyder, manager of the property. High-grade ore is being taken from the 700-ft. level, the deepest working in the mine. The last shipment to a Salt Lake Valley smelter averaged nearly 100 oz. silver and 48% lead, netting the company \$2700 for 27 tons.

Garfield.—The Garfield smelter is continuing operations, in spite of the complete cessation of operations at the Utah Copper Co. At present two reverberatory furnaces and one converter are in operation. The company recently made a large reduction in number of employees. At present the force numbers about 350. So far as local officials are aware, no shut-down of the plant is contemplated.

Moab.—The Tungsten Products Co., which owns and operates the extensive carnotite properties in Dry valley, has been consolidated with the Radium Company of Colorado, according to H. K. Thurber, field manager for the former company. The enlarged concern will be the largest producer of carnotite ores in the world. There soon will be an increase in production from the Dry Valley and Gateway mines.

Park City.—Ore shipments from the district for the week ending April 30 totaled 1450 tons, as compared with 1321 tons for the preceding period. The Judge companies shipped 761 tons; Silver King Coalition, 586; and the Ontario, 103.

Salt Lake City.—The United States Supreme Court, on writ of certiorari, will review the decision of the United States Circuit Court of Appeals in the case of the Snake Creek Mining & Tunnel Co. v. the Midway Irrigation Co. at Park City. This case involves the right to underground waters issuing from the Snake Creek tunnel. The District Court of Utah decided in favor of the mining company, but its decision was reversed by the Circuit Court of Appeals.

WASHINGTON

Keller.—J. E. Angle, superintendent for the Iron Creek Mining Co., recently found high-grade silver ore in an unexplored part of the property. The ore contains bromides, chlorides, and some sulphides. The company has been working five men all winter, and may erect a cyanide plant.

Spokane.—Lower freight-rates on ore shipped from the

Okanogan and Republic districts to the smelter at Tacoma, with a refund of claimed overcharges in the last two years, was asked of the Great Northern railway by the Arlington Mining Co. at a hearing by the Department of Public Works recently. Reductions in freight-rates asked range from 5 to 10%. The suit of the Arlington company is representative of all miners and shippers of ore in the two districts.

WISCONSIN

Platteville.—Mining in the Wisconsin zinc-lead districts is in a helpless condition and one from which it may be a long time recovering. Two mines operated by the Vinegar Hill Zinc Co., the Yewdall mine at Livingston, and the Unity mine at Day Siding, continued outputting low-grade zinc ore through the month of April, the ore going to the National

able. At the Penna-Benton mine in the Benton district a force of miners has been kept at work constantly and considerable ore is being mined and milled but no shipments are being made. The Black-Jack mine, in the Galena district, has been abandoned and the pumps removed.

Some improvement was shown in the offerings for zinc ore and lead ore the latter part of the month but it is of little material interest as there was but one company in the field in a position to take advantage of improved offerings, this being the Vinegar Hill Zinc Co., which made delivery of about 400 tons of high-grade ore.

BRITISH COLUMBIA

Rossland.—There promises to be greater activity here than for some time. The Consolidated company's mines are

Hauling Ore by Sled from Premier Mine

The Same Work Being Done by Caterpillar Tractor

Separators at Cuba City, for magnetic separation and the manufacture of commercial sulphuric acid. Early in the month the New Jersey Zinc Co. unexpectedly began pulling up the pumps at a number of mines, soon after, power, mining, and milling plants were being dismantled. The mines owned and controlled by the New Jersey Zinc Co. were producing regularly at the time of the shut-down last autumn and it is difficult to understand the apparent abandonment. At Mineral Point, where is an establishment, representing an investment of several million dollars, for the manufacture of zinc oxide and sulphuric acid, a force of men was kept at work until the middle of April. The sulphuric-acid works suspended operations entirely during April and the department making zinc oxide was run with a divided force, one-half of the men working each two weeks out of the month. It is rumored that the plant at Mineral Point will be dismantled and removed but no official confirmation is obtain-

operating, and recently Douglas Lay has arrived from London to assume the management of the Le Roi No. 2 mine, better known now as the Josie. Lay states that machinery for a concentrating plant had been ordered and would be erected as soon as it arrived. There is considerable ore in the mine that is too low grade for shipment directly to the smelter, and it is to handle this ore that the concentrator is planned. Mr. Lay at one time was in charge of the Van Roi mine, at Silverton.—The Rossland Velvet Mines, Ltd., has taken over the Velvet mine, and will push development and production during the year. Last year this property produced a considerable tonnage of ore running from 5% to 20% copper and \$10 to \$20 in gold.

Vancouver.—Work on the design of a new mill to replace the one recently burned at the Britannia mine has been started, and as soon as the plans are completed work on the mill will be started. It is feared that there will be difficulty

in obtaining delivery of some of the machinery, and it is not expected that the mill will be completed before the early part of next year. It is understood that the mill will not differ greatly either in design or capacity from the one destroyed. The Britannia company is in a strong financial position, and will not have to await the insurance settlement before starting work on the new mill.—A syndicate has been formed to develop a gold discovery at the Ellen group, Shuttle island, one of the Queen Charlotte group. The group was staked in 1918, but recently rich gold-quartz ore has been found.—A. J. T. Taylor, president of the Taylor Mining Co., is returning from England, where he went with the object of interesting capital for the erection of a concentrating plant and other equipment at the Dolly Varden mine.

Stewart.—T. A. Graham, of the Riblet Tramway Co., and four expert mechanics have arrived to start the erection of the aerial tramway for the Premier Gold Mining Co. Two carloads of machinery have arrived, and another carload was shipped from Seattle on May 6. The cables are being provided by John A. Roebling's Sons Co.; the running-cable will be $\frac{3}{4}$ in. and will come in 15,000-ft. lengths; the down-track cable will be 1 in. and the return $\frac{3}{4}$ in. Eleven and a half miles of the two last and 23 miles of the first will be required.—Albert Peterson and partner have commenced rawhiding ore from the Silverado group. The ore is said to assay \$1100 per ton.

MEXICO

Monterrey.—J. P. Flynn plans to start development work upon several claims in the Avino district upon which he recently filed. Mr. Flynn was formerly manager for the Avino Mines Co., a large producer of low-grade ore. The Prodigion group of mines in the Colorado district, State of Zacatecas, which has a good record of production, has been taken over by John J. Murphy, an American mining man of Chalchihuit. There are several rich mines in the locality.

Considerable interest has been aroused here over the announcement that the Mexican government has declared forfeited the old Santa Fe and Guadalupe mines in the Partido de Pinos district, State of Zacatecas, and that these properties have been filed upon by a number of Mexicans of the city of Zacatecas. The cause of the forfeiture is not explained.

The Topia Falls Mining & Smelting Co., of Topia, State of Durango, plans to develop a group of claims in that district if its application for title to same is favorably acted upon, it is stated. The claims adjoin the Santa Lucia and San Jose gold-silver mines. It is announced that several ore-reduction mills in the Pueblo Nuevo district, State of Durango, which were closed during the long revolutionary period, are to be repaired and again placed in operation. It is in this district that A. E. Miller is making preparations to start development upon the San Juan mines.—Mexican miners have filed upon the Guadalupe mines in the Inde district, State of Durango, which were recently declared forfeited for non-payment of taxes.

ONTARIO

Porcupine.—In addition to a general speeding up of activity in the producing area much interest is being shown in a widely extended outlying district surrounding the proved goldbearing territory. Active exploration has been commenced in many directions, and the field is likely to extend over a width of ten miles and a length of about 40 miles.

Toronto.—The Ontario government has withdrawn the bill introduced in the Legislature providing for increased mining taxation, owing to the strong opposition met in the mining districts. There is a general feeling of relief among mining men, as great apprehension was entertained that the passage of the measure would discourage investments in mining properties.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. B. Lakenan was at Salt Lake City last week.

Horace V. Winchell was at Salt Lake City recently.

W. C. Campbell has returned from Mexico to Toronto.

Bond Coleman has moved from Pachuca to Tampico, Mexico.

Jackson A. Pearce has returned from Santa Rosalia, Mexico, to Berkeley, California.

F. Benitez is with the Société des Mines de Cuivre de Catémou, near Chagres, in Chile.

A. J. T. Taylor, president of the Taylor Mining Co., has returned to Vancouver from London.

W. W. Wishon passed through San Francisco last week on his way to Quesnel, British Columbia.

London W. Bates, of New York, is at the St. Francis hotel. He is investigating the use of pulverized coal.

A. J. Ronaghan has been elected secretary of the Utah Copper Co. to succeed **K. R. Babbitt**, deceased.

E. P. Shove, secretary-treasurer of the Ray Consolidated Copper Co., has returned from China and Japan.

C. W. Corfield, chief electrical engineer for the Utah Copper Co., has returned to Garfield from New York.

T. A. Rickard will deliver the Commencement address of the Montana School of Mines at Butte on June 3.

E. J. Franklin, consulting mechanical engineer for the Ray Consolidated Copper Co., is at Salt Lake City.

R. Van A. Mills, petroleum technologist of the U. S. Bureau of Mines, was in San Francisco during April.

Henry E. Wood passed through San Francisco on his way from Los Angeles to the Cat Creek oilfield in Montana.

E. C. Lane, chemist at the San Francisco laboratory of the U. S. Bureau of Mines, has left for an extended Eastern trip.

J. Nelson Nevius is at the new silver district, Silverhorn, Nevada, doing geologic work for some of the companies operating there.

J. M. Bidwell, manager of the Utah Department of the American Smelting & Refining Co., has returned to Salt Lake City from New York.

Charles Bocking, manager for the Butte & Superior Mining Co. at Butte, is in New York. He stopped at Salt Lake City and St. Louis on his way.

C. F. Kelley, president of the Anaconda Copper Mining Co., accompanied by **B. B. Thayer**, vice-president, visited Butte and Anaconda last week.

C. V. Jenkins has been elected treasurer of the Utah Copper, Chino Copper, and Nevada Consolidated Copper companies. His headquarters will be in New York.

W. S. McCornick, the well-known banker of Salt Lake City, and prominently identified with the financing of mining companies during the past fifty years, submitted to an operation on May 3 for the amputation of his right leg above the knee. The operation was rendered necessary as a result of aneurism of an artery below the knee. While the operation was serious, owing to Mr. McCornick's advanced age, it is believed he will recover.

Albert C. Savage died at Guadalupe, Mexico, on May 3. For nearly thirty years he had been living in Mexico; for the last ten years he was in the employ of the Esperanza Mining Co., at El Oro. Last summer he was injured by falling from a horse, and this injury proved fatal. He was 73 years old, having been born in New York in 1848, the son of William Savage, one of the pioneer railroad men of the United States.

THE METAL MARKET

METAL PRICES

San Francisco, May 10

Aluminum dust, cents per pound.....	75
Antimony, cents per pound.....	7.50
Copper, electrolytic, cents per pound.....	13

Zinc dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

May 9—Copper is inactive and stronger. Lead is dull and higher. Zinc is quiet and steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

DECREASE IN OUR FOREIGN TRADE

The fall in world prices is an important factor in the recent reductions in the foreign trade figures of the United States. Now that we get the details of the March figures, says a statement by The National City Bank of New York, and are able to note the groups of articles in which the big falling-off occurs, it becomes evident that a large part of the reduction in 'total values' is due to the greatly reduced prices at which the merchandise entered or left the country.

March imports as a whole show a fall of 52% as compared with the same month of the preceding year, but when considered by groups, we find that 'raw material for use in manufacturing' shows a reduction of 62%, 'foodstuffs' 52%, and 'manufactures' 45%. This tremendous fall of 62% in the value of manufacturing material imported, suggests on its face that the manufacturers of the country have greatly reduced their activities, but when we examine the prices at which material of this character is being imported as compared with those of a year ago, the fall-off in 'total value' is less alarming. Cotton, wool, silk, and hides are the more important features of the group 'manufacturing material', and when we find that the average price per pound of cotton imported in February (the latest month for which price figures are available) averaged but 21c. per pound against 43c. in March of last year, the fall of 62% in 'total value of manufacturing material' seems less alarming. In many others of the raw materials conditions are somewhat similar: raw silk imported in February 1921 averaged only \$5.86 per pound against \$12.28 in March 1920; clothing wool 22c. per pound against 66c. in March of last year; combing wool 17c. per pound against 52c.; cattle hides 17c. per pound against 35c.; and calf skins 23c. per pound against 63c. a year earlier. In the foodstuffs group, in which the fall-off was 52%, raw sugar is by far the biggest factor, and the imports of February 1921 were at 4.8c. per pound against 8.3c. in March 1920.

On the export side, lower prices are also responsible for a considerable part of the big fall-off. The group 'raw material for manufacturing' shows in March 1921 a fall of 69% in total value when compared with March 1920, but when we find that the average price per pound at which raw cotton was exported in February 1921 was 17c. as against 42c. in March 1920, and realize that cotton is the chief factor in this group, the fall-off of 69% in value is in a considerable degree explained. Foodstuffs exported in March 1921 are 40% less than in March 1920, and a part of this is due to the fact that flour exports in February 1921 averaged \$14.7 per barrel against \$31.35 in March of last year; corn 85c. per bushel against \$1.60; dried apples 8c. per pound against 22c.; lard 15c. per pound against 27c.; and cottonseed oil 8c. per pound against 24c. in March of last year. Manufactures ready for use show a fall of 45% in the March exports as compared with those of March 1920, but when we find that unbleached cotton cloth exported in February 1921 averaged only 12c. per yard against 22c. in March 1920, and that a similar reduction runs through the cotton and many other lines, a part of this reduction in total value of manufactures exported is explained, though it is proper to add that the various classes of iron and steel manufactures, and those of mineral oil, show little reduction in 1920 prices as compared with those of the corresponding date in 1920.

MONEY AND EXCHANGE

Foreign quotations on May 10 are as follows:

Sterling, dollars:	Cable	3.99 1/2
	Demand	4.00 1/2
Francs, cents:	Cable	8.49
	Demand	8.53
Lire, cents:	Demand	5.26
Marks, cents		1.61

Eastern Metal Market

New York, May 4.

None of the markets is active, but a good tone prevails; prices are steady to firm in all cases.

Buying of copper is moderate; prices are steady. Japan has bought again.

Demand for tin is light; the prices are firm.

Lead has advanced but buying is not heavy.

The zinc market has turned quiet but quotations are steady.

Antimony is featureless and without change.

IRON AND STEEL

Recent comment in the consuming trade has indicated an expectation that price reductions made by the Steel Corporation, effective April 30, were transitional and the question has been raised whether a further decline might come in case the Corporation reduced wages. A partial answer, says 'The Iron Age', is the estimate that the 20% wage-reduction just announced represents \$4 per ton on full operation of Corporation plants. The price reduction of April 30 averaged \$7 to \$8 per ton. In the light of April's scale of operations it seems hardly likely that the earnings for that month can be much over half of those of March. Steel Corporation operations continue at less than a 40% rate. Whether the wage-reductions will cause hesitation in placing orders, in the hope of still lower prices, is yet to be developed.

Generally the better sentiment apparent in the industry last week continues. Further business from automobile makers is in part responsible for it, although this is largely the filling-in of gaps in stocks to produce salable products.

The April output of pig-iron was a daily average of 39,768 tons, or less than any daily rate since July 1908, when the country's capacity was much smaller. The total for the month was 1,193,041 tons, while that of March was 1,595,522 tons or 51,468 tons per day, itself a figure which was the lowest since late in 1914.

Fifteen furnaces were blown-out or banked in April, but nine were blown-in. The net reduction of six left 96 furnaces in operation on May 1, producing at a rate of 38,505 tons per day, against 102 on April 1, producing at a rate of 43,530 tons. On October 1, 1920, there were 319 furnaces in blast at a daily rate of 106,220 tons.

COPPER

Generally the market is inactive with domestic business confined to small lots for moderately early delivery, May-June. The only heavy buying has been another purchase by Japanese interests of about 1500 net tons, which makes the total purchased for the Far East in the last two or three weeks about 4000 tons. Quotations for electrolytic copper vary according to the sellers. There are one or two willing to sell at 12.62½c., delivered, for May; others hold at 12.75 and 12.87½c., delivered. The New York quotations are ¼c. under these. We quote the market at 12.37½c., New York, for electrolytic, with Lake copper at 12.75c., New York, both for May-June delivery. Forward positions are about ¼c. higher.

TIN

There are no features; the market is quiet and prices are steady to firm. Lack of activity is due to two causes: uncertainty as to the outcome in Europe and the initiation of the marine strike in this port. The principal buying of the week took place late last Friday, but the volume was not large; there were sales of spot and future shipment Straits tin at 32c. with a little May-June shipment changing hands at 32.12½c. on Saturday. Spot Straits has hovered around 32c., New York, the past week, with the quotations yester-

day at 31.87½c., New York. The London market was down yesterday about £5 to £6 per ton from a week ago, closing at £168 for spot standard, £170 10s. for future standard, and £175 per ton for spot Straits. The Singapore price yesterday was £179 per ton c.i.f. London. Deliveries into consumption in April were 1590 tons, with 2441 in stocks and landing April 30. Imports for the first four months were 5998 tons, against 17,783 tons to May 1, 1920. Tin afloat is reported as 1150 tons.

LEAD

The market is quiet, very firm, and without special feature. Another advance was made last Thursday, April 28, by the American Smelting & Refining Co. from 4.35 to 4.50c., New York and St. Louis, which represents the market, as that interest is regarded as supplying most of the demand, which is not heavy. It is recognized that any large buying could not be supplied by that producer, probably. Independent sellers are asking higher prices, 4.75 to 4.87½c., New York, with the St. Louis price at 4.50 to 4.60c. They are doing a little business at these prices. An interesting development is the arrival last week of 5000 tons of foreign lead, probably Spanish, at this port.

ZINC

The activity on the part of galvanizers that characterized the last two or three weeks has slackened. Producers are generally firm in their attitude and are holding firm in their ideas of prices and are not inclined to force the market. Many of them parted with their April output and are content to await May developments. Some are asking a minimum of 5c., St. Louis, for prime Western, but this grade can be bought in moderate quantities at 4.95c., St. Louis, or 5.45c., New York, which is the market. A year ago this country supplied 75% of the British imports of zinc, but now it is estimated that Germany is supplying 65% of that market.

ANTIMONY

The market is quiet and unchanged at 5.25c., New York, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted by the leading producers at 28c. f.o.b. plant, with the foreign grade of the same analysis quoted by other dealers at 23 to 23.50c., New York.

ORES

Tungsten: Inquiries are reported more numerous and the market shows improvement. Sellers are waiting tariff developments and are not ready sellers, especially at the buyers' ideas of prices. Chinese ore is quoted at 3.25c. per unit, with Bolivian and other grades higher or from \$3.50 up per unit.

Ferro-tungsten is inactive and nominal at 58c. per pound of contained tungsten in lump form, guaranteed quality.

Molybdenum: Regular concentrate is quoted at 55 to 60c. per pound of MoS₃ contained.

Manganese Ore: High-grade manganese ore is offered as low as \$22.50 per unit, seaboard, without takers. The nominal quotation is 25 to 30c. per unit.

Manganese-Iron Alloys: The markets for both ferro-manganese and spiegeleisen are stagnant. Quotations are nominal at \$90 delivered, for American ferro-manganese and \$32 to \$36, furnace, for spiegeleisen, 20%.

Ferro-chromium is quoted at 16 to 16.50c. per pound of contained metal in 6 to 8% carbon material.

Ferro-silicon, 50%, can be bought at \$80 per ton, delivered.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

Forestalling trouble

THE oxy-acetylene process builds up worn shafts, bearings and gears and remakes broken and cracked metal parts of all descriptions in the shortest possible time and at an exceedingly low cost.

Prest-O-Lite

DISSOLVED ACETYLENE

has enabled operators to apply the welding and cutting blow-pipes to every sort of reclamation work in and about mines because this highly pure gas is supplied in readily portable, instantly available cylinders which may be taken to any job, however inaccessible.

By keeping equipment constantly in perfect running order serious breakdowns are practically eliminated.

Prest-O-Lite Service operating through forty plants and warehouses insures a prompt and never-failing supply of Prest-O-Lite Dissolved Acetylene anywhere in any quantity.

DEPRECIATION in the market value of Government securities is illustrated in the annual report of the Miami Copper Company, the loss to the company as a result of the sale of such bonds during 1920 amounting to \$333,199.41. A mining company may be excused for parting with its Liberty Bonds before maturity; it is certain that when they were bought the rate of depreciation was not anticipated.

PHILADELPHIANS are proverbially slow, but, we venture to add, dependable. We are informed that a local Section of the Institute was organized in Philadelphia on May 16, this date having been selected because it was the semi-centennial anniversary of the founding of the Institute, an event that happened at Wilkes Barre, Pennsylvania, in 1871. The occasion was marked by an address from Dr. Henry Drinker, one of the founders of the Institute. Our friend, Mr. F. Lynwood Garrison, is secretary of the new Section, to which we wish good luck.

EFFICIENT fireproofing of underground workings is being recognized as a logical form of insurance. At the Anaconda Copper Mining Company's properties, according to the annual report, the value of a protective coat of 'gunite' is appreciated. During the past year cement-guns were used to coat the shafts at the Bell mine for a depth of 1681 feet, the main station and the power station at the 2800-foot level, all the magazines for powder, fuse, and caps in many of the mines, as well as many thousand feet of cross-cuts, mine-exits, and surface-adits of the shafts. Simplicity and ease of application are among the advantages of this method of providing a protective coating, which accounts largely for its increasing popularity.

REVIVAL of interest in gold mining is anticipated by keen observers abroad, as well as among our own people. For example, Sir William Dalrymple is quoted in the London 'Financial Times' as saying: "I cannot help thinking, in view of the strange conditions, industrially and financially, all over the world and the impossibility of countries to buy or provide money for improvement schemes entailing the use to a large extent of base metals, that investment in sound gold production is much safer and more reliable in the matter of profit for

the next two or three years." With this we agree, although an improvement in the copper market, to which we look forward confidently, will restore a large measure of activity to that branch of the mining industry also; indeed, mining generally is bound to come to its own as the process of deflation comes to an end and the normal expansion of industry makes its demand on the production of the metals. So long as civilization endures, there will be need for metals.

OPINIONS amount to but little unless they are voiced, and voiced to those who should hear them. Mr. J. N. Houser, the general manager for the Tennessee Copper Company, reports that he is continuing the practice of meeting with a large committee of the employees about once a month, for the discussion of matters of individual and mutual interest and concern; the result has been that the entire organization is co-operating to a degree that is creditable to all concerned. Too much attention cannot be paid to the advantages of frequent personal contact; it generally results in the avoidance of mistrust, it increases confidence, and it usually leads to an appreciation of the fact that industrial operations are, or should be, carried out for the benefit of employer and employee alike.

RAILWAYS are an important factor, not only in opening up new mining districts, but in throwing the spotlight of enlightened public opinion on mining enterprises and on the manner in which they are conducted and managed. We learn with interest, from a consular report, that a contract has been signed between the Government of Bolivia and one of our engineering firms, for the financing and construction of a railway to connect Atocha, in Bolivia, with La Quiaca, in the Argentine, a distance of 126½ miles. The road is to be completed by August 1, 1925; the cost will be met by a loan of \$7,000,000. Previous concessions to French and Argentine firms have lapsed on account of non-fulfillment; the consummation of the project is now assured. The completion of the road will give South America its second transcontinental railway, which will be especially welcomed, not only during those periods of heavy weather when the Santiago-Mendoza line is unworkable, but at all times to mining engineers and travelers who wish to cross the Andes without going so far south as

Valparaiso, and who wish to visit Bolivia on the way. The new road will serve two excellent purposes besides: it will give Bolivia an additional outlet to the coast; and better communication with the mineral deposits of Bolivia will, it is hoped, induce the Argentine authorities to pay more attention to the development of their own country in this respect. As our friend Mr. W. E. Simpson once remarked, the mining engineer in Argentina is classed as a sort of confidence-trick man who can hypnotize his listeners with entrancing reports of limitless wealth in some inaccessible region, and get them to part with their cash while under the delusion that they are being enriched. Direct rail connection with a prosperous mining region will do much to restore Argentine confidence in an industry that is at least as legitimate as agriculture.

THE annual report of the Dean of the graduate school of the University of North Carolina, Dr. Edwin Greenlaw, contains so many pertinent truths on the subject of research that it is deserving of a wider audience. The modern university, he insists, is concerned with the addition to knowledge as well as the transmission of knowledge. The vitality of the university depends on the proper balance of these functions. There are many who maintain that research is not within the province of the State university, which they would limit to utilitarian work. There are others who maintain that research in the true sense is only possible in the richly endowed universities, in urban centres, where great libraries and laboratories are available; it is profoundly true that scholarship, in order to be effective, requires honor, freedom, and material resources. Contempt for the research man or a perfunctory attitude toward his work, a burden of committee and class-room labor that saps his vitality, the lack of the materials whereby he may carry on his investigations—these kill the spirit of research. On the other hand, a great library and laboratory equipment may be used only in a perfunctory way, or not at all. There are all sorts of research men, as there are all sorts of senators, or business men, or physicians. Genius is a matter of the spirit and of the intellect. Where the spirit is present the results somehow come. The field for service, says Dr. Greenlaw, lies in quality, not in numbers. The purpose is not to attract a miscellaneous collection of degree-holders who want another degree, but to find the superior student who will do superior work. A small group of students who are certain to attain distinction in research will enable the University to render a service that would otherwise be impossible if a race were attempted with other universities for superiority in numbers. Given a group—not a large group, for the world's supply of such men is small—all of whose innermost life is bound up in research and in the creation of the spirit of research in young men, and the future is assured. Writing with reference to material encouragement and support, the Dean says that "even when salaries are advanced, high-school and college teaching cannot compete, in the material rewards

that are regarded as tests of a successful career, with commerce and the other professions. The one and only hope for meeting this competition lies in the development of a passion for research, for the things of the mind, for learning as a divine calling. Transformed by a new idealism, it will become the great and abiding hope for bringing about that respect for scholarship that is to enable us to meet the challenge of a material civilization. . . . Business organizations are ready to employ brilliant young graduates at salaries that were unheard of a few years ago. The very type of man who would, other things being equal, devote himself to research, is most certain to be confronted by the subtle temptations of salary and of worldly opinion. Our service depends on our ability to hold the first-rate man, not the second- or the third-rate one". In other words, research, which after all is nothing more than the occupation of the scientist, deserves encouragement, sympathy, and facilities; it must be carried out by men of keen analytical and dispositive minds, men with experience, knowledge, perception, logic, and a capacity for unlimited perseverance; nothing will be achieved by making it a means of livelihood for mediocrities.

THE committee appointed by the Mining & Metallurgical Society of America to consider the question of post-graduate education, consisting originally of Messrs. R. Gilman Brown, Fred Hellman, R. C. Gemmell, Pope Yeatman, and later including Professor Robert Peele and Mr. H. H. Knox, has rendered its report. Mr. Brown, as chairman, is a resident of London, and so was able to gather first-hand information and to form sound conclusions as to the success of the scheme of post-graduate education that was launched about nine years ago by the Institution of Mining & Metallurgy. The conclusions reached by the chairman were that the British plan had been a success, that it fills a definite want peculiar to the country but almost non-existent with us; the success, in Mr. Brown's opinion, has been due largely to the fact that the Institution "is fortunate in having a permanent, whole-time official [Mr. Charles McDermid, the secretary], possessing a high personal standard, coupled with rare tact and personal magnetism in dealing with young men" as well as, we would add, with the older members of the Institution. The realization of the importance of personal influence and sympathy has led Mr. Brown to propose a scheme of post-graduate assistance for would-be mining engineers in this country, by which "the true aims of professional life could be brought into their proper perspective; an idealism fostered that would be practical and not the mere chasing of rainbows; mere money-getting as such put second to the duty owed through our profession to our fellows; less thought of what we get from our work by recognizing that those receive most who give most; a perception that some wealth costs too much". This 'godfather' idea assumes the proper selection of graduates, and also the place of their work. The men who will undertake the task must be volunteers, they must be

mature, of sympathetic nature, wise, and of high ideals; and they must be ready to find leisure to devote to their godsons. There should be, as Mr. Brown points out, a sufficient number to whom such idealism appeals, who feel impelled to some other achievement than mere material success, and who are convinced of the duty of service. It is hoped that the proposal will meet with the support it deserves.

GENERAL satisfaction will be felt among members of our profession at the confirmation of Mr. Bain's nomination as Director of the U. S. Bureau of Mines. A few days ago many of us were surprised to hear that his nomination was endangered by the fact that the two senators from California were unwilling to endorse it. By custom, entitled 'senatorial courtesy', a citizen of a State cannot be appointed to an office needing confirmation by the Senate if a Senator from his State blocks the way. Mr. Bain is not a politician and therefore was a person of no consequence to the Senators from California, whose sum total of political patronage was reduced by the appointment of a mining engineer from California to the Directorship of the Bureau. In effect, they said, "Who is this Mr. Bain, we don't know him", and thereby the confirmation of the appointment was held up. This is the way the spoils system works. If the Senators did not know Mr. Bain, it was their fault, not his. He had lived in California, honorably and prominently, for eight years before he went to London as editor of 'The Mining Magazine' and to China as a consulting engineer for an American syndicate. During the War he came home to serve as assistant to the then Director of the Bureau of Mines, Mr. Van. H. Manning, and acquitted himself so well that general pressure was brought on him to accept the position when Dr. Cottrell resigned a temporary tenure of the office. The Senators from California might have known this if they had cared to be well informed on the subject; they had only to ask the Secretary of Commerce or the Director of the Geological Survey to learn all about Mr. Bain that it was necessary for them to know before acquiescing in his appointment. Instead, the president of the American Mining Congress, the president of the Engineers Club of San Francisco, the State Mineralogist, and others had to send telegrams to the Senators, assuring them that Mr. Bain was highly regarded by the mining engineers and mine operators not only of California but of the entire country. However, all's well that ends well. The incident served chiefly to accentuate Mr. Bain's high reputation and the esteem in which he is held.

A Company Meeting

The annual meetings of mining companies in London are usually rather stupid affairs, to which the chairman contributes a labored speech, reminding one of Milton's angels, whose speeches we read with respect and end with relief. The ensuing remarks of the shareholders usually disclose an abysmal ignorance of mining. Indeed the whole performance is steeped in bathos, and

seems to give to mining the touch of opera bouffe that Mr. Algernon Moreing ascribed more particularly to an Italian venture many years ago. Such was our mood when we started to read the account of the Camp Bird meeting as reported in the 'Financial Times' of April 21. First came the speech of the chairman, Mr. F. A. Govett, a gentleman who in times past has provoked a smile by his humptiousness, but who has lived down the effects of an excessive self-appraisal by his sincerity of purpose and his achievements as a leader of mining finance in the City of London. On this occasion he acquitted himself well. The company was in dire trouble; he told the shareholders the exact position, frankly and fairly. The drop in the price of silver had put an end to the profits from the Santa Gertrudis mine in Mexico, a fire had stopped production for several months before the silver market collapsed; then, when repairs had been made, a drought had caused a shortage of electric power, and, of course, a further decrease of profitable activity. Besides this the company had used its accumulated profits in subscribing heavily to the shares of the Mexican Corporation, the National Corporation, and the Mexican Chemical & Metallurgical Company, all three of which were started during a hectic boom, in the expectation that the improvement in Mexican political conditions was the precursor of a period of mining expansion. In these undertakings the Camp Bird company has contingent liabilities, on subscriptions not yet fully paid. A new mine, or group of mines, was purchased recently at Pachuca. This, the El Bordo, is looking most promising, but the shortage of power has compelled a severe cut in the capacity of the mill, which was to have been completed in June. Construction of the mill was stopped in February. It was, as Mr. Govett said, "a history of unforeseen disasters", and it came to a climax at a time when the coal strike had plunged England in the deepest depression. He told the story manfully: "The only thing to do is to face the facts and see it through", with that bulldog tenacity, we venture to say, that never loses its grip and never accepts defeat. The British may call it "muddling through", but no foreigner is entitled to apply the phrase contemptuously, because, after all, it involves qualities of heart and mind that command our respect. Mr. Govett rose to the occasion finely; he was followed by a director, Mr. F. H. Hamilton, whom we happen to know. He is an accomplished speaker and a witty one. If the world was "tumbling to pieces", as Mr. Govett had implied, then "nothing much matters", he said. "It is a more profitable question for us to ask ourselves: 'Supposing it is not, what then?'" Thereupon he reminded the shareholders that, if the world was not tumbling to pieces, they had a splendid organization, rich mines, and big interests in Mexico. He himself felt more optimistic than he had felt at any time in the last six months: "One cannot help seeing that in the catastrophic fall we have had in all commodities the turn of the tide seems to have come." As we read the account of this meeting we feel impelled to extend a friendly hand to our mining

friends across the water. We on this side have troubles of our own, notably the temporary collapse in copper mining, but our misfortunes are light compared with those which hang so tenaciously to the shoulders of the mining fraternity in London, for there the slump in mining is part of political and industrial complications which have been so persistent that even a brave soul might well begin to despair. They will not despair; of that we are certain; they are not made of despairing stuff. We wish them better luck heartily, and believe that it will come in due course.

The German Reparations

It seems that the latest conditions formulated by the Supreme Council of the Allies are to be accepted by the German government. We say "it seems" because there is no positive assurance that the German policy of postponement and evasion may not yet defeat the effort to make an end of the miserable wrangle. The total sum is equivalent to 33 billion dollars, at the normal rate of exchange. A tax of 26% is to be levied on exports, of which 1% is to be set aside for a sinking-fund and 25% is to be applied to the interest on the three bond issues into which the entire sum of reparations is to be funded. A sum of two billion gold marks, or \$480,000,000, is to be paid yearly in redemption of these bonds. As to whether 33 billions is excessive, it needs to be remembered that the payments are spread over 42 years and that the present value of the reparations at the usual rate of interest is only about 12 billion dollars. Further, it has been acknowledged in the Reichstag that the German government that waged the war had intended to exact 30 billions from the United States, a similar sum from Great Britain, and 40 billion dollars from France, not as reparations for damages actually done but as punitive indemnities. We believe that the demand made upon Germany is just and that she can afford to pay it. As soon as the bonds are issued, in furtherance of this international settlement, we shall hear all about Germany's resources and her ability to make good, as we believe she can, if she sets herself honestly to do so. German industry is well on its feet and is competing successfully in the world's markets. "Germany can put a ton of steel in England at a price \$20 per ton cheaper than England can make it", says Mr. Charles M. Schwab. Pneumatic tools from Germany are now being sold in Detroit, says the same authority. Unquestionably the rate of exchange as between the mark and the dollar or pound is such as to offer great advantage to the German manufacturer and he will avail himself of it, of course; indeed, the heavy reparations will serve to foster German foreign trade, particularly in South America and the Orient. That was one reason why the Labor party in England opposed the exaction of adequate reparations, fearing the consequence would be to flood the world with goods of German manufacture and to throw the workers in other countries out of employment. The next question is, who will buy the German bonds? The distribution of reparations to the

Allies is fixed in the proportion of 52% to France, 22% to the British Empire, 10% to Italy, 8% to Belgium, and the remainder to Japan, Portugal, and others. Presumably the Allied governments will wish to transfer the German bonds to this country in exchange for our exports to them. It is unlikely that England or France will guarantee the German bonds, unless the United States prove willing to accept them in payment for existing loans, but such a transaction would, we think, meet with general disapproval among our people. An offering of German bonds without the guarantee of the English and French governments would be a failure except at a discount large enough to incite speculative buying; they would hardly rank higher than German currency, which is at 6% of parity. We fear that these German reparations may make trouble yet. Judging from the behavior of the Germans since the Armistice, it seems unlikely that they will abide manfully by their agreements in this matter, so that we may expect delays in the payment of interest and possibly a repudiation, under the cloak of necessity, of the contract. The German scrap-book is a notable volume already. Any delay or repudiation in the matter of the successive payments due under the reparations agreement will provoke the Allies to coercion, military and economic, and will thereby sow the seeds of future conflict. Fortunately our Government acted unequivocally and firmly in refusing to be used as a cat's paw by Berlin; indeed, the reply made by President Harding, through the Secretary of State, contributed largely to the settlement, by bringing the moral pressure of the United States into action just when it was needed. If in the future, as in the recent past, the United States should indicate that it will refuse to assist Germany in any tricky evasion of her obligations, it may be possible to prevent trouble, meaning warfare in Europe, on this account. Only a just firmness on the part of those who brought the War to an end can prevent an unrepentant Germany from bringing another vast horror upon a sad and weary world.

Destructible Power Resources

The question has been raised as to what extent the present generation should assume a moral responsibility in the matter of the conservation of the natural products that give us heat and energy, the destructible resources of power. Are we to assume that future generations will, by invention and discovery, or by the development of hitherto unrecognized sources of power, make good the wastage occurring at the present time? Or should we restrict our consumption of destructible heat-giving material with an eye to the needs of future generations, and without assuming a continuation of the same rate of inventive and scientific progress that has characterized the 19th and the earlier years of the 20th century? The fact cannot well be overlooked that we are profligate in the consumption of our national assets. Our automobiles numbered a million and a quarter in 1914, and nearly eight millions at the end of 1920; to keep them supplied with fuel we are, to some extent, 'burning the candle at

both ends'. In an attempt to justify ourselves let us examine the possible sources of future supply of power and heat.

The reserves of coal are such that there is no need for immediate apprehension; but extraction is becoming increasingly costly. The domestic consumption of gasoline for 1920 exceeded that for 1919 by over 800 million gallons; it exceeded that for 1918 by considerably over one billion gallons. The world's production of petroleum in 1920 was 688,474,251 barrels, according to the American Petroleum Institute. This represents a gain of 24.2% over the 1919 production. The production in the United States increased from 377,719,000 barrels in 1919 to 443,402,000 barrels in 1920, a gain of 17.4%. The production is now five times what it was in 1901; and this is insufficient for our needs. The significance of the increased demand is seen in largely increased imports. Mexico supplied us with 110,000,000 barrels in 1920, as compared with 57,000,000 barrels in 1919, a gain of 93%. Stocks of oil are being drawn upon as if we were facing a national emergency, the proportion of oil in storage to oil consumed having decreased 5% during the past year; it now represents less than a four-months supply. Fuel-oil is a vital necessary for any country that can boast of a large navy, a large army, or a large military air service. How can future requirements in this respect be assured? At the present rate of consumption the supply from existing sources will show serious signs of diminution within a few decades, assuming no further discoveries of importance. Oil will be developed in other countries, and additional supplies, doubtless, will be forthcoming. The automobile and the motor-truck have come to stay, but their demands have been such that deep inroads have been made into the fuel resources of the world. The rubber requirements of the industry were unconsciously anticipated by a bold adventurer who took the seeds from Brazil in 1876. Today there is an extensive rubber industry in the Eastern tropics, we have learned to re-use salvaged material, and supply exceeds demand; but we have not been able to grow the fuel needed for the millions of rubber-tired vehicles that over-run the country. Substitutes for gasoline are already being used, however. In the district around Pernambuco, in Brazil, there is a thriving sugar-cane industry. The recent high price for gasoline has drawn attention to the value of alcohol for use in internal-combustion engines; and this is now being produced in quantity as a by-product of the sugar mills. Certain disadvantages were apparent at first from the use of the pure spirit, notably in connection with the inability to cause rusting of certain parts of the motor; but this is now prevented by the addition of 5% of gasoline to the alcohol, the mixture forming a standard motor-fuel. It can be obtained at less than half the cost of gasoline, and its value for power purposes is enhanced by the fact that combustion is practically complete, so that there is less 'carbonizing' in the engine. Other cheap and efficient substitutes for gasoline will, we have no doubt, make their appearance from time to time, as the price of the normal article becomes higher. The effect is a concomitant to the cause. The increased demand brings

a realization of a comparative shortage of supply. The price is raised; by some it is considered prohibitive; and a substitute is introduced.

The practicability of utilizing the heat that is known to exist within the interior of the earth is a moot point. As far as high temperatures are concerned, the outer crust has only just been scratched by our mining operations, comparatively speaking; nevertheless, temperature problems are factors that have to be considered in some of the deep mines. Rock temperatures in different mines show that the increase with depth may not be regular. At 6000 feet below the surface in the St. John Del Rey mine in Brazil, the deepest in the world, it is about 115°F.; at 4000 feet it is about 98°F.; so that there is, roughly, a rise in temperature of 1° for every 117 feet of depth. At the City Deep mine, in South Africa, the rock temperature at the 6000-ft. level is given as 89°F.; at 8000 feet it is assumed to be 97°F., showing an increase of 1° per 250 feet of depth. It is obvious therefore that temperature will vary according to locality; in volcanic districts it may be higher than in other places. In certain parts of the world, notably in the Mediterranean region, steam is given off from the ground. Boreholes are made in much the same way as for the drilling of oil-wells, and the steam is utilized for generating power. The presence of steam at the surface of the earth, however, suggests instability; hence it is probable that the power requirements of modern civilization would be small at such a locality. Generally speaking, it may be assumed that we must go a long way in the direction of the centre of the earth if we wish to tap a source of power for industrial operation. The problem has been considered, if not studied. Sir A. C. Parsons, the inventor of the steam-turbine, is credited with the suggestion that a 12-mile shaft would reach a region underground where an almost unlimited amount of heat would be available. It is suggested that this heat might be utilized by the installation of an exchanger, consisting of steel piping that would be used to carry a liquid, of a higher boiling-point than water, to the surface and back again, and that would continuously take up heat from the lower part of the shaft. Problems of no mean magnitude would be encountered; but the idea is no more fantastic than some of the achievements in the 'fairy' tales of Jules Verne must have seemed fifty years ago, but which have since been developed, largely by the aid of electricity, into actualities.

The sun gives off a vast amount of heat, but very little of it is utilized. Successful results are said to have been achieved in Egypt from the practice of heating thin layers of water in closed vessels exposed to the rays of the sun, the heat thus obtained being utilized for power purposes. But Saharas are uncommon and uninviting. Industry does not thrive in such places, and the demand for power would be negligible usually. However, there are exceptions. One of the largest industries in South America is situated on the Chilean pampa, in an arid region, where the sun's rays are scorching, where the atmosphere is abnormally dry, and where high winds are common. There is practically no rainfall. Atmospheric

conditions are exceptionally favorable for solar evaporation, as practised in the salt flats of Utah and California, for instance; it is therefore an amazing fact that practically all the evaporation, and this constitutes one of the major expenses of nitrate recovery, is achieved by the use of steam from oil-fired boilers. In considering the available power resources of the world the fact must not be overlooked that simplification as well as economy may result from the saving of fuel. Boiling in open vats may serve the purpose, vacuum-pan evaporation may be highly efficient when a utilization of the calorific value of the fuel only is being considered, but the sun's rays are there for the taking; and Nature has provided air currents that ensure continual movement and effective evaporation. This evaporation is the source of all our water power, which is merely transformed solar energy. The water in the ocean is evaporated, lifted up, condensed, and deposited at higher levels. In falling again toward the level of the ocean it is made to perform useful work—to drive turbines and water-wheels. These in turn operate electric generators, producing a current that may be used to melt steel. Can the heat production of the sun be duplicated, on a reduced scale, on this planet? To what is it due? Kelvin estimated that a mass of burning coal, the size of the sun, would be consumed in 5000 years; but it is evident that the sun has been giving off its heat for an infinitely longer time than this. The result of the investigations of the Curies and other scientists on radioactive elements offers food for thought and speculation: transmutation is no longer classed among the absurdities of legendary times; it is an accomplished fact. One ounce of radium will give off an amount of energy equivalent to that obtained by the combustion of 10 tons of coal; the emanation will continue for the space of 2500 years. So far, scientists have been unable to retard or to hasten this action; but they have discovered that, in wasting away, another element, helium, is produced. It is not improbable that we are on the threshold of discoveries of vast economic importance. The presentation of one gramme of radium to Madame Curie is one of the most significant tributes to pure science that modern history can record.

Wind-mills are not used to anything like the extent they might be. This is due largely to the fact that they are often of so flimsy a construction that one is inclined to think that their application is limited to farm work. The power obtained in proportion to the capital expended is small, of course; and the output is variable. Nevertheless, there are many places where they could be introduced, and where fuel would be saved. The action of the tides suggests a source of power. The subject is one upon which some misconception exists, so that a few explanatory details will not be out of place. Newton's law of attraction presupposes that the force of gravitational pull is inversely proportional to the distance intervening. Both the sun and the moon attract the earth; but the moon, being nearer, exerts the greater pull. The water of the ocean is sucked into a heap, as it were, at certain places, the earth underneath the water being

subject to a less attraction because of greater distance. Thus we get high tides directly underneath the moon, and low tides at a circle of the earth that is 90° from the sublunar area. At the same time, the sun, with a force equal to about one-third that of the moon, also forms tidal crests of lesser magnitude. Hence we have two low and two high tides every 24 hours and 51 minutes, the fraction of the hour beyond the day being due to the movement of the moon in an easterly direction. When the moon is 'new' or 'full' it is in a direct line with the earth and sun; exaggerated 'spring' tides are the result. When the moon is at half or one-third, it is at right angles to the sun; low or 'neap' tides are the result. It must be explained that tides, as we understand the word, are not due to the immediate action of the sun or moon, but upon transmitted movements that occur, primarily, several thousands of miles away. The rate of such transmission of tidal effect is said to approximate 7000 miles in 12 hours. It has been estimated that the maximum tidal movement in the centre of the Pacific area amounts to 1.95 feet, of which 1.34 feet is due to the attraction of the moon and 0.61 foot to that of the sun. The movement, therefore, is small at the source. How can tidal flow be utilized to give power? In the first place, unusual estuary conditions are essential. At the entrance of the Bristol Channel, the range of ordinary 'spring' tides is 23 feet. At the end of the channel, where the river Severn commences, the rise is 40 feet. Tides of 53 feet have been recorded at Chepstow Bridge. Narrowed channels, therefore, cause an exaggeration of tidal effects: and there are instances where it would seem that an enormous amount of power is going to waste. The subject is being investigated in Great Britain. It is proposed to build an immense barrage, or dam, across the river Severn. The idea is not new, it was first proposed in 1843, but lack of funds prevented the consummation of the scheme. The present proposal, which is still in a preliminary stage of consideration, will probably involve an expenditure of about £15,000,000 for machinery alone. The output, translated into electric energy, is estimated at 260,000 kilowatts per 10-hour day; the cost of current will amount to about 0.4 penny per unit. Power-plant manufacturers are disinclined to co-operate. The equipment required is not of standard design; the load will fluctuate to an abnormal degree; the static head will vary between 6 and 36 feet. Tidal waters are usually heavily charged with silt; and a mechanical problem is introduced that demands attention, not only on account of turbine wear, but also because of the accumulations that are liable to occur in the reservoirs and behind the dams. The geology of the district is to be studied, and attention is to be paid to the probable effect of an increased current. However, greater problems than these have been solved in other branches of human endeavor. Hydro electric power-plants are usually successful installations: both from the economic as well as from the mechanics standpoint. Hope may be expressed that the success of the new Severn scheme will lead to a better appreciation of the untapped power resources of the world.

DISCUSSION

Valuing Partly Exhausted Mines

The Editor:

Sir—I read Mr. Morton Webber's recent articles on this subject with much interest, and with approval in most respects. His program of dividing the preliminary development into three stages, the prosecution of each stage depending on the success of the preceding one, is particularly commendable in that it provides for predetermined points in the progress of the work from which the entire project may be reviewed in the light of newly acquired information.

My chief criticism of the paper is that it assumes throughout that the prospective value of a mine lies in the downward extension of ore-shoots exposed in old workings. Examples A and B are both vein deposits. If the entire workings are shown in the illustrations, the drifts have been driven practically no distance beyond the limits of the ore-shoots and apparently the possibilities of finding other ore-shoots along the veins have not been tested by the original operators, nor advised under recommendations for new work, except inadequately in Example A, on Level No. 4. In this example, if Level No. 2 were not caved, its extension to the east would appear to be advisable, but if practical considerations should prevent drifting on this level, then Level No. 1 and Level No. 4 should be driven a very considerable distance. Exploration eastward on Level No. 1 might be obviated by prospecting the outcrop by means of trenches. If it shows no signs of mineralization, work on Level No. 1 may be omitted. Mr. Webber mentions the existence of old stopes to the east. These, if they are near-by, may obviate the necessity for further exploration on Level No. 2; but at the same time their presence strengthens my contention, that, based on the illustration alone, considerable development to the east is desirable.

In Example B, the development work shown outside the orebody is obviously inadequate. The occurrence of an orebody of this size would surely justify the expense of considerable work in search of other ore-shoots in the same vein. The termination of the ore-shoot near the 900-ft. level is only an indication of the vertical depth to which ore may be expected. This should be checked against similar data from other mines in the district, if such exist. But even though commercial ore should be limited to this depth, the possibility of finding other ore-shoots in the same vein or in other veins on the property is a point fully as worthy of investigation as that of extension at depth. Unless there is evidence to the contrary, the prospective value of a partly exhausted mine

may be more in the chance of finding new orebodies than in developing the extension of old ones.

Mr. Webber's statement, "Unless there is collateral evidence from neighboring operations, the exhausted portions of the deposit are the only index to the possibilities of the future", overlooks such evidence as the extent of the outcrop and its character, the existence of other veins on the property, especially if they are reasonably near the original vein and parallel to it. It is not uncommon in the case of two parallel veins to find an ore-shoot on one directly opposite to that on the other. Indeed, in these days of few newly discovered mining districts, it is thought by many that the most favorable localities in which to search for ore are those in which large orebodies have previously been found; and collaterally, that a good place to look for a new ore-shoot is somewhere near one that has already been found. The exhausted portions of a deposit may be taken, however, as an index of the character and grade of other orebodies in the near vicinity, or in a less degree, in the adjoining district.

Horizontal rather than downward exploration has been a successful means of finding ore in many mines. At Tonopah, Nevada, large quantities of ore were found in the Tonopah Mining Company's property by lateral development. It is a matter of common repute that an eminent engineer made an adverse report on the property early in its history, because the ore-shoots then opened did not extend below the 700-ft. level. That was over 17 years ago and the property has been operated continuously and successfully during that time, largely on parallel veins above the 700-ft. level. In the Nevada Wonder mine, at Wonder, Nevada, the original ore-shoot was bottomed at 1000 ft., but an exploratory drift driven 1200 ft. along the barren part of the vein to the south opened a blind ore-shoot that produced \$2,000,000. At Oatman, Arizona, there is a series of five or six valuable shoots of gold ore spaced along the Tom Reed-United Eastern vein. Without a liberal policy of development by drifting, any one of these shoots might have been mined without discovering the others. The point I would make is that, in valuing a partly developed mine, the appraisal of the chances of finding new orebodies is of the utmost importance.

A detailed mapping of geological features is of great assistance in valuing a property, and if possible it should be done before the sampling. Together with the sampling, it will form the basis for the appraisal, not only of the developed or partly developed orebody, but also of the chances of finding other orebodies. An understand-

ing of the geology will often result in a more intelligent sampling; and may suggest points where, because of faults or branching veins, a small amount of development work during the sampling may lead to important results. In fact, it is not a bad thing for the sample-boss to be something of a geologist himself.

I have no doubt that these matters are fully appreciated and practised by Mr. Webber, but his article is under review, and in discussing it, I feel that it is worth while to advance these supplementary considerations.

Referring again to Mr. Webber's article, I call attention to the fact that where waste rock is used for stope-filling, a practice much more common now than formerly, a small mine-dump is no indication as to the amount of dead work, or of selective mining. Where the mine-dump is large, it may indicate extensive exploration, and strong stope-walls that stand without filling, as well as the things specified by Mr. Webber.

Further, I question the statement that "a mine should be able to earn 7% on the cash investment". That seems inadequate. There would be few mining enterprises of small or medium size initiated if there were not the expectation that the entire capital and a reasonable profit would be returned within a few years. An annual return of 15% is a common demand, but in the case of short-lived mines, it should be larger.

JOHN A. BURGESS.

San Francisco, April 25.

Assessment Work

The Editor:

Sir—Why this suspension of assessment work on mining claims; whom does it benefit? Surely not the legitimate prospector or mine-owner. The owners of the principal mines or claims in this district have not been benefited by the suspension or extension of assessment work, as they are on the ground, pegging away on development, and have their work done early in the year, before the 1919 and 1920 laws were passed, and most of them have done enough work this year to cover their 1921 assessment.

There are only three claim-owners in this district who have not performed their assessment work for 1920; and two of them, I have reason to believe, intended to abandon their claims if the time had not been extended to July 1, 1921. They are not in the camp and have not started any work up to date. Their claims or fractions of claims should or could be justly annexed to other groups or holdings that are trying to revive the camp.

The suspension and extension of assessment work have done injustice to the industrious prospector and claim-owner. There is too much of the public domain blanketed by speculators, people who never intend to do any assessment work and are only retarding gold mining.

If the time for assessment work is again suspended or extended the claim-owners that did their work should be compensated.

W. K. WHITMORE.

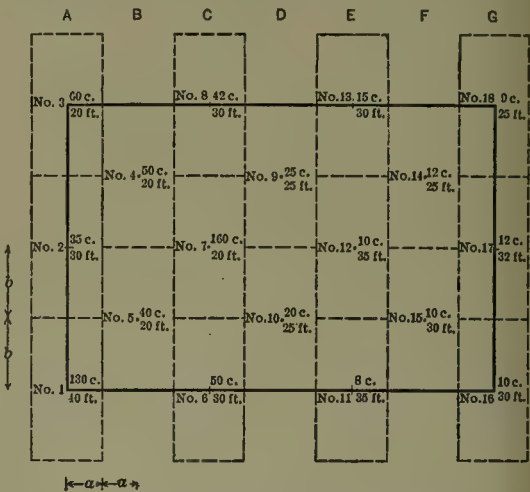

Mohave, California, April 25.

Method of Calculating the Average Value of Placer Ground

The Editor:

Sir—James T. Dixon's method of calculating the average value of placer ground is described by Eugene B. Wilson in his 'Hydraulic and Placer Mining' (pp. 39-44, 3rd edit.); the original plan being shown below.

The heavy dots are 18 drill-holes; the value of gold from each hole is marked on the top in cents per cubic

yard, and below it is marked the depth of the hole in feet to bedrock. The ground to be valued is limited by the lines connecting 1, 3, 18, 16, and 1.

A modified form of calculation, which saves much arithmetical work as compared with Dixon's way, is given in the following tabulation:

	Depth	Volume	Cu. Yd.	Product
1	$a \times b \times 40$	$= 40ab$	$\times 130$	$= 5200ab$
2	$a \times 2b \times 30$	$= 60ab$	$\times 35$	$= 2100ab$
3	$a \times b \times 20$	$= 20ab$	$\times 60$	$= 1200ab$
4	$2a \times 2b \times 20$	$= 80ab$	$\times 50$	$= 4000ab$
5	$2a \times 2b \times 20$	$= 80ab$	$\times 40$	$= 3200ab$
6	$2a \times b \times 30$	$= 60ab$	$\times 50$	$= 3000ab$
7	$2a \times 2b \times 20$	$= 80ab$	$\times 160$	$= 12800ab$
8	$2a \times b \times 30$	$= 60ab$	$\times 42$	$= 2520ab$
9	$2a \times 2b \times 25$	$= 100ab$	$\times 25$	$= 2500ab$
10	$2a \times 2b \times 25$	$= 100ab$	$\times 20$	$= 2000ab$
11	$2a \times b \times 35$	$= 70ab$	$\times 8$	$= 560ab$
12	$2a \times 2b \times 35$	$= 140ab$	$\times 10$	$= 1400ab$
13	$2a \times b \times 30$	$= 60ab$	$\times 15$	$= 900ab$
14	$2a \times 2b \times 25$	$= 100ab$	$\times 12$	$= 1200ab$
15	$2a \times 2b \times 30$	$= 120ab$	$\times 10$	$= 1200ab$
16	$a \times b \times 30$	$= 30ab$	$\times 10$	$= 300ab$
17	$a \times 2b \times 32$	$= 64ab$	$\times 12$	$= 768ab$
18	$a \times b \times 25$	$= 25ab$	$\times 9$	$= 225ab$
Total				$1289ab$
Average				$= 45073ab \div 1289ab = 34.96c. \text{ per yard}$
Area				$48ab$; Average depth, $1289ab \div 48ab = 26.85 \text{ ft.}$

Average value of the ground $= 45,073 \text{ ab} \div 1289 \text{ ab} = 34.96 \text{ cents per cubic yard.}$

Area being 48 ab ; average depth $= 1289 \text{ ab} \div 48 \text{ ab} = 26.85 \text{ feet.}$

Gold-Digging Ants

The Editor:

Sir—This story of Herodotus, referred to in your address on 'Prospecting', published in your issue of April 23, has been classed among the products of pure imagination for 2000 years, but it is founded on facts, as are many other fantastic stories of the old writers. Marco Polo, for example, was long regarded as a champion liar, but the more the investigations have been made in the countries he describes the more he is found to have been an accurate and truthful narrator.

Herodotus has been called the Father of History, and also the Father of Lies, but, while he repeats without guaranty many wild tales, some have been founded on fact. In a journey to Egypt a few years ago I was much amused to see what an accurate and careful observer Herodotus was and how tenaciously the Egyptians have clung to the customs so accurately described by him.

The story to which you refer is found on pages 214 and 215 of the Bohn edition of Herodotus, and is to the following effect:

"There are other Indians bordering on the city of Caspatyrus . . . they are the most warlike of the Indians and these are they who are sent to procure the gold; for near this part is a desert by reason of the sand. In this desert then, and in the sand, there are ants in size somewhat less indeed than dogs, but larger than foxes . . . These ants, forming their habitations underground, heap up the sand, as the ants in Greece do, and in the same manner; and they are very like them in shape. The sand that is heaped up is mixed with gold. The Indians therefore go to the desert to get this sand, each man having three camels, on either side a male one harnessed to draw by the side, and a female in the middle . . . When the Indians arrive at the spot, having sacks with them, they fill these sacks and return with all possible expedition. For the ants, as the Persians say, immediately discovering them by the smell, pursue them, and they are equalled in swiftness by no other animal, so that if the Indians did not get the start of them, while the ants were assembling, not a man of them could be saved."

This seems a perfectly absurd story, but in one of the publications of the Geological Survey of India, I find the following account.*

"Of the very highest interest are the accounts of the Thibetan gold mines, which are given by the pundits attached to the Indian Survey for the purpose of exploring the countries north of the Himalayas. Unwittingly these admirable native servants of the Government of India have furnished facts which have enabled Sir Henry Rawlinson, and, independently, Professor Frederic Schiern, Professor of History of the University of Copenhagen, to clear up a mystery which has been a puzzle to the historians and philosophers of many countries for upwards of 2000 years. A translation of Professor Schiern's paper, by Anna M. H. Childers will be

found in Vol. IV of the 'Indian Antiquary'. It is a most remarkable example of learned research and one very difficult to give in abstract. It is entitled 'The Tradition of the Gold-digging Ants'. But perhaps before giving the conclusions which Sir Henry Rawlinson and Professor Schiern have arrived at, it will be best in this place to briefly describe the pundits' observations.

"During the expedition of 1867 the pundit who had been at Lassa fell in at Thok Jalung with a large encampment of Thibetan miners, and took the opportunity to gain information relative to the working of the mines. In the third expedition, in 1868, another pundit passed on as far as Rudok, at the north-west extremity of Chinese Thibet on the frontier of Ladak, and on his way back from Rudok he visited the goldfields of Thok Nianmo, Thok Sarlung, and Thok Jalung.† The map which accompanies Major Montgomery's narrative of the journeys of the pundits gives in addition the goldfields of Thok Munnak, Thok Ragyok, Thok Ragung, and Thok Dalung . . . The miners' camp at Thok Jalung, according to the measurement of the pundits, is 16,300 ft. above the sea-level. The cold is intense and the miners in winter are thickly clad with furs.

"The miners do not merely remain underground when at work, but their small black tents, which are made of a felt-like material, manufactured from the hair of the yak, are set in a series of pits, with steps leading down to them . . . seven or eight feet below the surface of the ground . . . Spite of the cold the diggers prefer working in the winter; and the number of their tents, which in the summer amounts to 300, rises to nearly 600 in the winter. They prefer the winter, as the frozen soil then stands well, and is not likely to trouble them much by falling in.

"They are occasionally attacked by robbers, who carry off their gold."

Sir Henry Rawlinson, a noted scholar and the first to decipher the cuneiform inscriptions of Assyria, remarks on these reports of pundits' researches and travels as follows:

"Now for the first time we have an explanation of the circumstances under which so large a quantity of gold is, as is well known to be the case, exported from the west to Khoten, and finds its way into India from Thibet; and it is probable that the search for gold in this region has been going on from a very remote antiquity, since no one can read the ex-pundit's account of Thibetan miners, 'living in tents some seven or eight feet below the surface of the ground, and collecting the excavated earth in heaps previous to washing the gold out of the soil', without being reminded of the description which Herodotus gives of the 'ants in the lands of the Indians bordering on Caspatyrus (or Kashmir) which made their dwellings underground, and threw up sand-heaps as they burrowed, the sand which they threw up being full of gold'."

*'A Manual of the Geology of India', Part III, Economic Geology, by V. Ball, Calcutta, 1881, page 213.

†Ball says that the pundit passed a great excavation 30 to 40 ft. deep, 200 ft. wide, and two miles long, from which gold had been extracted.

Professor Schiern points out that the tradition was mentioned in writings of the Middle Ages, and those by Arabian authors. It survived among the Turks. Strabo and Albertus Magnus treated the whole story as a fiction. Xivrey supposed that the animals had become extinct owing to the *auri sacra fames*. Major Rennell supposed that the dwellers in mounds were *termites* or white ants. Humboldt's observations in Mexico on the habits of certain ants to carry about shining particles of hyalith was quoted by those who believed that the animals were really ants. Other authorities suggested that they were marmots, jackals, foxes, or hyenas. Pliny having stated that the horns of the Indian ant were preserved in the temple of Hercules at Erythrae, Samuel Waehl, who maintained the hyena theory, proved equal to the difficulty by suggesting that the horns might have been a *lusus naturae*. Professor Schiern ingeniously argues that horns had been taken from the skins of animals that formed the garments of the miners. It seems possible, however, that they were samples of the pickaxes made of sheep's horns, which, as is mentioned above, are used to the present day by the miners in Ladak.

Professor Schiern further points out that ancient writers say that the ants worked chiefly in winter, and connects this with the statement of the pundit above quoted. In conclusion he writes:

"For us the story partakes no longer of the marvelous. The gold-digging ants were originally neither real ants, as the ancients supposed, nor, as many eminent men of learning have supposed, larger animals mistaken for ants on account of their subterranean habits, but men of flesh and blood, and these men Thibetan miners, whose mode of life and dress were in the remotest antiquity, exactly what they are at the present day."

The latest account that I have seen of these goldfields of Tibet is in the appendix to Waddell's 'Lhasa and its Mysteries'; he states that the large gold mines undoubtedly exist and extend over 300 miles in one long tract, the principal workings being at Thok Jalung N 32°24', E 81°38'; and in addition to this tract others are known.

Palo Alto, April 28.

Prospecting

The Editor:

Sir—Permit me to say a word in behalf of my old pals and myself in reference to prospecting, or rather lack of prospecting, in these times. The scribbler of these lines has spent some 25 years in the field and ought to qualify as the genuine article.

That prospecting as we know it, that is, actually looking for mineral, has narrowed down to the vanishing point cannot be denied. Staking sagebrush claims we have never recognized as prospecting, and that is about all one sees nowadays. Such 'properties' are eagerly sought at times whenever a mushroom boom is started by the professional promoters who issue these worthless stocks to the public, and I am sorry to say that often the

leading business men, bankers, and professional men lend their names as bait, for a block of promotion stock. A glance at the long list of Divide companies and the names of the directors will substantiate my statement. This, in my opinion, is mainly responsible for driving the genuine prospector from the field, because these fake promotions absorb the money that would in part at least go to the man actually digging.

Other causes are hard to define, but it has been almost impossible of late years to interest capital in prospects. Your mahogany-legged engineers seem to expect us to find and turn over to them properties fully developed, which cannot be done by a man working alone and without means. If you would bear in mind that the prospector also must eat, you would not make so many foolish breaks regarding the decline in prospecting.

To sum up briefly, just what is crowding the prospectors slowly but surely out of the field? I will name a few causes: fake mining companies, free option bums, lack of financial support, and last, but not least, the high cost of grub, tools, and powder. Right here I wish to make a plea for my old pals. We are most of us getting on in years and cannot compete with younger men, mostly foreigners, in the mines in earning grubstakes as we used to. What I ask of the fraternity is, if you are taking over a property don't break his heart by insisting on months of waiting for first payment. This often causes real hardship and suffering, too much of which has crept into our lives of late years.

E. M. WEST.

Topopah, Nevada, April 28.

The Editor:

Sir—I like to read your paper, and note your request to "chip in". Yes, if you will give us prospectors a square deal. I can tell you why we don't open new strikes. First, there is a strip 40 miles wide, and in lots of places 60 miles wide, half of which is owned by the Southern Pacific railroad, two thousand miles long from Cottage Grove, Oregon, to Imperial Valley, California, and more in other States, which means millions of acres or square miles. The Government claims the mineral, because the mineral was not given to the railroad. Congress is 80% lawyers and that strip makes lawsuits. Second, where are the grubstakers? The men that will gamble on a man to find a mine. Gone? Not much! The old storekeeper or the old banker or the saloon-man or hundreds of others, gamblers, farmers, stockmen, livery-stable men that got stuck for meals. No; they are all of them still taking a chance. Where? How?

Now let me tell you. And it don't help you engineers either. Hundreds of you fellows are out of a job because it is so. The men that took a chance in the old days are taking a lot longer chances now, all of them, the little grubstake man and the big one. They buy stocks on margins. They get quick returns. We prospectors are going fast. They make money once in a while but lose more often—sell long or buy short or some way. But where do the engineers get off? and where can a fellow

get a grubstake! Stop the damned stock-gambling. Third, the gold is here. Help stop the curse. They will grubstake all of us that didn't die with the flu. Pass a law so the railroad can get 10% and the Government 5%, and give us a chance at the railroad lands in California, Oregon, Washington, and Idaho.

Stop the gambling that develops nothing and produces nothing but suicides. It is the curse of the age. Stop it!

F. W. WRIGHT.

Los Angeles, April 29.

Mining Opportunities in Northern Mexico

The Editor:

Sir—There are two railroad building projects in Mexico that are of vital importance to the republic, strategically and commercially—strategically for they will serve to unite the capital and the eastern half with the isolated western portion; commercially, for they are vital to the development of the empire of fertile coast plain along the Gulf and along the Pacific and to the mines lying in the Sierra Madre. The Southern Pacific of Mexico, constituting the Mexican connection of the Southern Pacific system, begins at Nogales and taps the most important ports of the west coast of Mexico, runs the entire length of the coastal plain, crosses to connect with the Guadalajara branch of the Mexican Central, and thus finds ingress to the national capital. This railroad will stand as a monument to the energy and foresight of Epes Randolph, who, through revolution, flood, fire, Indian warfare, and world-war conditions, has pushed the construction of this great line of commerce. When completed it will compare, not unfavorably, with the achievement of James J. Hill in the north. It forms the main link in the Panama-California line, which is now no longer a dream; it might be a link in an Alaska-Valparaiso railway.

The other important line is the Kansas City, Mexico & Orient, from Kansas City to Topolobampo. This line lacks a short stretch between Creel, Chihuahua, and Fuerte, Sinaloa. There are many mines along this route that have been famous for centuries; many new discoveries await the incoming of capital which is now gaining confidence in the ability of President Obregon to bring Mexico back to stability and reason. The early resumption of the construction of this line is said to be assured, and when work is begun, the boom that will come to the districts near the Sonora-Sinaloa-Chihuahua corner will be notable. Many companies that now struggle with the hard problem of pack-saddle transportation, inspired by the possession of large bodies of rich ore, will come into bonanza when this line comes to their relief. The El Fuerte Mining & Smelting Co., in Sinaloa, has a cluster of immense orebodies carrying gold, silver, and copper, within reach of the smelting plant now being installed at the Mesa Colorado on the Fuerte river.

The Lluvia de Oro mine lies a little farther to the east, higher in the main backbone, and has produced gold for years. The Aguila company, owned principally by Kansas men and fathered by W. H. Seamon, of El Paso,

is about to pack in heavy machinery, as did the Lluvia company. The famous old 'Boss' Shepherd mines of Batopilas, the *antiguas* in and around Urique, and countless others, lie in this great mineral belt; the man who does not mind roughing it cannot fail to secure possession of attractive properties to offer the Pullman traveler, who will soon be able to come to this field. The present low ebb on the metal market may serve to check temporarily the ardor of mining investors, but those who fail to cast their eyes about, when faint-hearted ones hesitate, often lose opportunities to secure ground-floor chances. One of the world's greatest mining fields lies almost at our very doors, in the Sierra Madre country of northern Mexico.

Slosson's 'Creative Chemistry'

The Editor:

Sir—Your editorial note on Dr. E. E. Slosson's 'Creative Chemistry' in your issue of April 23 is properly appreciative, and I agree that it is the kind of popular scientific book that Huxley would have liked to read. But Mr. A. W. Allen's long review in the same issue would give a reader a different idea of the book; he picks all manner of flaws in it, and says little of the virtues, which are overwhelmingly more important than the flaws. That sort of book-review is all too common in American periodicals. Such a reviewer disregards the outstanding importance of a really valuable new book and sets forth unrepresentative details on which he can hang his own hobbies. Naturally when an author daringly and commendably gives to the public a much-needed synthesis of recent knowledge, he cannot get everything exactly in the proportion and aspect to please everybody. Learning has become so subdivided and its parts so specialized that it becomes increasingly difficult for an author to make a readable synthesis of facts on any broad subject; and for the same reason it becomes increasingly easy for a specialized critic to pick flaws in a technical book that appeals to the public.

When I get hold of a book like Slosson's 'Creative Chemistry', or Wells' 'Outline of History'—with all its faults—I feel like singing a paean of praise to the author. Then when I read reviews of the book by specialists who misrepresent it in their zeal for disputing incidental points that have caught their eagle eye, I think of Carlyle's sarcasm about the "critic fly" on a "brave stately building" and how it declared "with its half-inch vision, that here is a speck, and there an inequality; that, in fact, this and the other individual stone are nowise as they should be". The same keen-worded Scotsman remarked further that if 'Oedipus Tyrannus' were now discovered and staged for the first time, the critics would have their column of flaws to enumerate. "Was not the whole affair rather 'heavy'? . . . Did not Oedipus somewhat remind us of a blubbering school-boy, and Jocasta of a decayed milliner? . . . And so on, through all the variations of the critical cornpipe". Few great

authors are as omiscient as their critics. For instance, Nicolaus Copernicus' 'De Revolutionibus Orbium Celestium', published in 1543, kept to the old Greek assumption of uniform circular motion of the planets, necessitating an elaborate system of epicycles. This whole detail was wrong, yet the book of the Polish canon of Frauenburg has been of the greatest value to the world, and is important for the statement of the heliocentric theory regardless of minor errors.

While speaking of book-reviewing, I recall recently reading an interesting letter to the editor of some periodical (possibly the Literary Review of the New York 'Evening Post') in which a librarian ranked the reviews in the British weekly 'Nature' as the best he knew of. These reviews tell what the book is about, how it treats the subject—popularly or technically—and what special offering of material or method the author brings. Such information is what the reader usually wants. Unfortunately too many reviews have to be painfully puzzled over before the reader can obtain this information, for reviewers like to miss the main point for the sake of jumping on incidental slips. "In this way", said Carlyle, "does the small Reviewer triumph over the great Authors".

P. B. McDONALD.

New York University, April 26.

Book-Reviewing

The Editor:

Sir—Mr. P. B. McDonald's comments on book-reviewing, with especial reference to my review of Dr. Slosson's 'Creative Chemistry', are inaccurate and contradictory. He is inaccurate in stating that in the review I said little about the virtues of the book; he is inconsistent in advocating a system of book-reviewing that would practically confine the reviewer to making a résumé of the book, and that, in the present instance, would have prevented me from stating "the author, who is a chemist as well as an editor, is to be congratulated on the appearance of an excellently written, well-edited, and informative treatise" and from acclaiming 'Creative Chemistry' as a book that "will . . . take its place among serious efforts to enlighten and educate the average man on the progress of the art, and the achievements of chemical specialists"; it would have been impossible for me to have drawn attention to the fact that "the industry is fortunate in being able to call on writers like Slosson and Hendrick, both of whom possess the knowledge, as well as the happy knack, of being able to impart it in an entertaining manner"; I should have refrained from reference to what I considered as "the generosity of the author, as well as the catholicity of his views"; and, in anticipation of Mr. McDonald's ideas on reviewing, I should not have stated that 'Creative Chemistry' "prompts the reader to think. It is educational and written in a delightful style".

Mr. McDonald tells us that when he gets hold of a book like 'Creative Chemistry' he feels like giving a paean of praise to the author. Such an attitude, how-

ever, is likely to result in an unbalanced review. The critic is too often carried away by his enthusiasm under such circumstances, as Mr. McDonald was when he reviewed 'Creative Chemistry' a little while ago in the columns of 'Engineering and Contracting', in which he credited the chemists with the production of guayule rubber as a synthetic achievement, and emphasized, by repetition, Dr. Slosson's mistake of referring to the new chromium-steel alloy, used largely during the War for aeroplane valves and applicable to many other phases of engineering work, as "stainless cutlery". My impression is that authors of note, like Dr. Slosson, would not welcome a review of this kind, as compared with one in which a frank tribute is paid to the ability of the author and the merits of his book, coupled with a constructive criticism of what, in the reviewer's opinion, should receive attention before the next edition is published. Mr. McDonald favors the non-critical review in the same communication in which he refers to 'Creative Chemistry' "with all its faults"; and yet his own published review of the book makes no mention of these faults, but, on the other hand, is fulsome with critical appreciation.

I question Mr. McDonald's estimate of criticism in the United States; to me it appears to be almost as extinct as the dodo; it isn't done. Unworthy books appear and meet with a reception that is neither hot nor cold; new issues of excellent treatises are published in which the mistakes in the first edition have not been corrected; papers galore are presented at meetings of technical societies that fail to elicit either criticism or discussion; it simply isn't done. The fact that adverse comment may be made in an entirely friendly way is recognized only by an insignificant minority; by far the greater proportion of people consider that a fair and just criticism is to be interpreted as a personal affront—an act of ill-will, rather than, as it should be interpreted, as an evidence of intelligent interest and a desire to assist in strengthening that foundation of truth on which all real knowledge rests.

A. W. ALLEN.

San Francisco, May 6.

A HIGH-GRADE NICKEL ORE has been found close to the talc mines, north of the branch line to Barberton, Transvaal, South Africa. A. F. Crosse, in a recent issue of the 'Journal' of the Chemical, Metallurgical, and Mining Society of South Africa, describes the ore as a new and undescribed mineral. An analysis gave:

	%
Oxide of nickel	40.30
Oxide of iron	49.30
Phosphorus	0.13
Calcium oxide	0.20
Silica	6.50
Loss on ignition, chiefly water.....	2.15
Loss	1.45
Metallic nickel	29.6
Metallic iron	35.7
Platinum	0.2 dwt. per ton

A bar of nickeliferous iron, which was smelted direct from the ore, assayed 25% nickel.

THE STAR POINTER SHAFT

Nevada Consolidated Mining Company—III

Underground Mining at Ruth

By Arthur B. Parsons

INTRODUCTION. The thickness of the leached cap that overlies the ore deposit in the Ruth mine of the Nevada Consolidated company varies from 110 to 540 ft. and averages more than 410 ft. In lateral extent it is approximately 1600 by 1200 ft. and it is roughly oval in shape. As delineated by systematic churn-drilling, the thickness of the greater part of the ore-zone ranges from 40 to 310 ft., with an average of 120 ft. The ore is of comparatively uniform grade; and the ore and cap-rock alike are unusually soft; accordingly it was evident at the outset that some method of caving would be used for mining the ore.

The outstanding feature of the underground mining is the evolution of the branch-raise caving system now employed with exceptional success. Credit for the satisfactory results is due largely to W. S. Larsh, the present superintendent of underground mining operations, who introduced the system in 1915 and who has had immediate supervision of the work since that time. In initiating the work Mr. Larsh had the assistance of Robert Marsh Jr., who was general mine superintendent in 1915, and he has always enjoyed the invaluable advice and hearty encouragement of C. B. Lakenan, general manager for the company. Mr. Larsh, himself, is unstinting in the credit he gives to the members of his staff for their assistance in working out details of the

scheme of procedure and in conducting current operations. The development of the method will be discussed under four heads as follows: (1) the attempt to use the Ray system of shrinkage-stope and pillar-caving, and the reasons for its abandonment; (2) the adoption of the branch-raise system and an outline of the ideal procedure; (3) the method of regulating and recording the 'draw', that is, the removal of the ore from the different chutes tapping a block of ore; and (4) the application of the system or method to the mining of the entire orebody.

THE RAY SYSTEM. This is the method used successfully in the Ray Consolidated mine at Ray, Arizona. During the latter half of 1915, when production from the Ruth mine commenced, and for part of 1916, this plan was tried on a block of ground above the 300-ft. level from the Ruth inclined shaft. Following the Ray method, a series of long narrow stopes 10 to 15 ft. wide was completed at 25-ft. centres, thereby leaving a corresponding series of pillars having approximately the same width as the stopes. As soon as the stopes had reached the upper limit of the ore, the pillars were blasted from beneath; when the ground caved, the worthless overburden was allowed to follow the ore as it was drawn off below. The working-level from which the mining was done was a sub-level 30 ft. above the main motor-haulage drifts. On the sub-levels the ore was trammed by hand

in drifts spaced at intervals of 25 ft. and running at right angles to the long dimension of the shrinkage-stopes and also to the main haulage-passages on the level below, with which connection was made by chute-raises and manway-raises at frequent intervals.

However, the ground in the Ruth mine proved to be 'weaker' than had been expected and the expense involved in keeping open the hand-tramming drifts on the sub-level was great. It was necessary to replace timbers frequently, thereby increasing the cost of labor excessively. On the other hand, it was observed that the haulage-drifts, although they had to be closely and strongly timbered, were far enough below the zone of active mining to escape, or at least to withstand, the shifting pressure. Using the Ray system it would, of course, be possible to have placed the principle haulage-ways at a greater distance below the working-drifts; but this would not have obviated the great expense of keeping the latter open. It appeared on the other hand that the vertical and inclined openings were maintained without unreasonable expense; accordingly a practicable plan was sought for doing away with the intermediate levels by the substitution of a greater number of raised connections. The development of the present system and the abandonment of the attempt to use the Ray method ensued.

THE BRANCH-RAISE SYSTEM. The scheme for attacking an ideal block of ore, the bottom of which is assumed to be a horizontal plane, is illustrated in Fig. 1.* The haulage-way at the bottom is one of a number of parallel drifts driven at intervals of $87\frac{1}{2}$ ft., the track-level being 60 ft. below the bottom of the orebody. In actual practice the distance between the haulage-level and the 'point of draw' ranges between 40 and 80 ft., but 60 ft. is standard. Calculations based on the estimated cost of drifting and raising on an angle of 50° with the horizontal showed that with respect to the cost of drying the necessary working-openings the most economical distance between the haulage-drift and the bottom of the mining-zone was 40 ft. It was decided, however, that the horizontal pillar intervening between the top of the drift and the draw-level, if 40 ft. were selected as the standard height, would be so thin as to necessitate additional expense for maintenance. Calculations for 50, 60, 70, and 80 ft. showed that 60 ft. required less expenditure for making the necessary openings than any of the others, and it was accordingly adopted as the standard.

It should be explained that the angle of the branch raises, 50° , is the first factor determined; it is fixed and the distance between the main motor-haulage drifts and the vertical distance between the drifts and the draw-level are adjusted to meet this requirement. In a chute that is too steep, soft ore has a tendency to pack and cement itself in huge masses that must be broken by blasting or by expensive work with bars; or it may arch in the chute. On the other hand if the slope is not great enough the ore 'hangs up' and must be helped along con-

tinually, this tendency being exaggerated with soft ore such as is handled in the Ruth mine. The most advantageous angle has been proved to be 50° ; and so important is this question of slope that no deviation is permitted.

The ideal measurements accordingly are $87\frac{1}{2}$ -ft. intervals between haulage-drifts and the 60-ft. distance between haulage and draw-levels, thereby permitting the branch raises to slope at 50° , as shown in the figure. A 'raise-series', as the set of branches shown in section 4A, Fig. 1, is called, is started at intervals of 25 ft. along the direction of the main haulage-drifts. Special timbering, termed a 'pony-set', Fig. 2, provides a chute and an argate on each side of the drift. The branches are raised and timbered with 4 by 12-in. or 6 by 12-in. cribbing, the selection depending upon the character of the ground. Each raise has a chute-compartment 3 by 4 ft., inside dimensions, and a manway 2 by 3 ft. At the top of each branch, immediately over the chute-compartment, is a vertical square-set framed of 10 by 12-in. or 12 by 12-in. timbers. From this set are built two cribbed finger-raises, as shown in detail in Fig. 3, and diagrammatically in Fig. 1. These fingers, according to the early practice, consisted of four or five sets of cribbing, but this was found to be too much. Three sets at a somewhat lower pitch afford the necessary spread and make work more convenient for the miner who is drawing ore.

It is apparent that the centres of adjacent square-sets are $12\frac{1}{2}$ ft. apart in the plane of each raise-series. Since the finger-raises diverge in planes at right angles to this, the result is a checkerboard arrangement of draw-points, formed by the finger-raises, spaced $12\frac{1}{2}$ ft. in both directions. The imaginary plane, which is the locus of the draw-points, is known as the draw-level; theoretically it coincides with the bottom of the ore deposit.

Three or four raise-series are completed before drawing can be started in a particular block; the succeeding series are 'brought in' consecutively, one at a time, the rate depending upon the demand for ore-production. It is not desirable that the development by raises should be far in advance of actual mining because of the cost of maintaining the raises. As mining operations advance the ore is under-cut by miners working in the finger-raises, the amount of such work depending upon the local nature of the ground. The attempt is always made to connect all the finger-raises in each row of the series and to run cross-cuts between alternate fingers of the two rows, as shown in Fig. 1. This leaves a row of narrow pillars to be drilled and blasted as the final step in completing the under-cut, over a given raise-series; it is always best to under-cut completely in order to assure uniform caving. Unless a new block is being started there is the shattered ore overlying the previous raise-series to which cross-cuts may be run and to which the remaining pillars can break. In some parts of the mine it is frequently necessary to stope 15 or 20 ft. above the draw-level in order to start caving; on the other hand, the ground may be so greatly shattered that it is impossible to complete the under-cut, and a dozen long holes,

*After Walter S. Larsh. Trans. A. I. M. E. Vol. LIX. Page 299.

FIG. 1. SKETCH SHOWING IDEAL CAVING OPERATIONS

drilled from the 'fingers' and fired simultaneously, start the caving satisfactorily.

Occasionally blocks covering an area of several hundred square feet settle without breaking. These obviously must be broken up before the drawing can proceed properly; a small stope started within the huge piece has frequently served as the best way to break it up. In general, however, according to Irving Van Dalsem, the energetic chief engineer of the Ruth mine, to whom I am indebted for my information concerning many details of the operation, the caving of Ruth ore is not a difficult part of the problem. Moreover, it is characteristic of the cap-rock that it caves readily and follows the ore uniformly. This is one of the essential characteristics of a deposit that can be mined successfully by any caving method. Incidentally, it may be pointed out that this system of mining probably could not be used advantageously at Ray for the reason that the orebody there is so solid that it could not be depended upon to cave, without the weakening effected by shrinkage stopes. On the other hand, there is nothing inherent in the nature of the Nevada Consolidated orebody to prevent the successful use of the Ray method; the question is simply one of comparative cost.

REGULATING AND RECORDING THE DRAW. Good results

depend entirely on the care with which the ore is drawn from the different finger-raises. Both Mr. Lakenan and Mr. Larsh are emphatic in declaring that inattention to this feature has been the cause for unsatisfactory results in nearly every instance where branch-raise mining has been tried without entire success. Two things are sought: first, to get all the ore; second, to leave all the cap-rock, which, of course, tends to mix with the ore, which it follows down. The only way by which an idea of the condition of the caved mass of ore and waste can be obtained is by keeping a detailed record of the ore taken from the stope at each draw-point, and by checking this against the 'expectancy' from that point.

The expectancy, that is, the quantity and grade of ore that should be recovered from a given finger, is calculated from data obtained in churn-drilling, close approximation being possible because of the absence of wide or sudden fluctuations in the tenor of the ore. Sundry charts are made to record the estimates thus obtained and finally the information is displayed graphically on a simple but ingenious model. This consists of a group of perpendicular steel rods about 3 ft. high and $\frac{1}{8}$ in. diameter fixed in holes in a large wooden base, the surface of which is laid out to scale to represent a block of ore being mined. Each rod is situated at a draw-point. On the rod is an adjustable collar that can be slipped up or down and fastened in any desired position by means of a small set-screw. At the start the

FIG. 2. A PONY-SET AND ORE-CHUTES

expectancy data are used to determine the height of the individual rods, the tops of which represent the position of the plan of separation between the cap and the ore-body.

A daily report is made showing the quantity of ore drawn from each raise by the motor-men, together with an estimate by the draw-bosses of the amount taken from each finger. The stope-engineers adjust any discrepancies in the figures and credit the draw-points with proportional parts of the total reported by the motor-men. Daily samples are taken of the ore from each raise-series

and assay reports, and in diagnosing difficulties, much of this work falling to J. P. Caulfield Jr.; the foreman. By temporarily stopping or decreasing the quantity taken from certain draw-points and increasing that from others they are able to control the operation with remarkable success. It is desirable to draw slowly from a comparatively large area, rather than to remove narrow blocks by hurried drawing.

The following data are typical records from the monthly report. It will be observed that the draw from Raise No. 22½ has been completed.

Level 500, Block I. Month of December 1917										
Raise No.	Expectancy		Reserve Dec. 1, 1917		Ore extracted		Reserve Jan. 1, 1918		Total extracted	
	tons	grade, %	tons	grade, %	tons	grade, %	tons	grade, %	tons	grade, %
22½	34,127	2.25	2,339	2.25	3,320	1.79	35,108	2.10
22½	39,964	2.20	14,107	2.20	6,821	1.64	7,286	2.20	32,678	2.09
23½	38,284	2.31	21,160	2.31	11,401	1.82	9,759	2.31	28,525	2.08

and, in the event of unusual behavior, from individual fingers. These assays, of which an average of 100 is taken each day, are combined with the figures on tonnage, and, after the charts are brought up to date, the information is transferred to the model, that is, the collars are lowered by the amount represented by the ore drawn. There will be irregularities, of course, but the result is a fairly reliable graphic record of the current position of the top of the caved ore. The stope-engineers prepare a sheet every evening for the foremen, showing the quantity that should be drawn from each finger next day. The system of recording was devised by Mr. Larsh and his assistants, and is credited by him as being the principal factor in the success of operations.

The 'angle of draw' is the slope, from the horizontal, of the plane of contact between broken ore and waste in the direction of successive raise-series. Experience has shown that this angle should be maintained at approximately 40° for the best results. If this angle be steeper, the difficulty of preventing the admixture of waste rock is increased, whereas if it be less steep, a longer period will elapse from the time a block is started until it is finished. This entails extra expense in keeping the raises open and the timber in repair. There is the disadvantage of having an excessive quantity of ore broken in advance; it tends to pack tightly and must be loosened again. In the other direction, that is, in the direction of the successive fingers from the same raise, the contact-plane is, in general, kept horizontal.

'Contact-plane' suggests a smooth surface dividing the ore and waste. In practice the maintenance of such a plane is impossible, as can readily be imagined; the purpose of regulating the draw is to approach such a condition as nearly as possible. Tongues of ore will reach up into the cap-rock and may be lost; on the other hand, channels may form so that cap-rock gets down to a particular draw-point long before the expectancy from that point has been realized. Occasionally an arch will form over a finger and cannot be blasted, so that drawing from this point will necessarily be delayed. The remedy is to attack the 'choke' from adjacent fingers by blasting the large pieces that cause the trouble. Mr. Larsh and his staff have become adepts at interpreting the daily draw

An idea of the final result may be obtained from the following figures covering all portions of the orebody that had been completely mined at the conclusion of the year 1920.

Expectancy		Actual recovery		Excess of	
tons	copper, %	tons	copper, %	tons, %	Deficit of copper, %
3,580,757	2.15	3,747,249	1.95	4.6	4.9

These figures do not show the tonnage shipped up to that time, for the reason that blocks that were only partly mined are excluded from the calculation. They indicate, however, that excellent results are being obtained. The admixture of waste in the ore shipped amounts to 9.1%; of this, 95% is virtually barren, the cap in the Ruth mine differing in this respect from that at Ray, Inspiration, and Miami, where most of the cap-rock contains appreciable amounts of copper. The high net recovery made by the Nevada Consolidated therefore is particularly meritorious.

APPLICATION OF THE BRANCH-RAISE SYSTEM. The orebody, speaking generally, is lenticular in shape with a dip of 15° to the north-west. However, the limits of the minable ore are irregular in both vertical and horizontal directions, thereby presenting sundry interesting problems in planning the details of mining. The general scheme is to place the drifts from which the branch raises start in such a manner that the draw-level, 60 ft. above, will coincide everywhere with the bottom of the ore. This height varies between the limits of 40 and 80 ft., but, as stated before, the standard is 60 ft. The interval between the levels must, to correspond, be 60 ft. On each level a principal haulage-way is driven from the Star Pointer shaft to the theatre of actual mining; at right angles to it are the various working-drifts, which follow roughly the contour of the bottom of the orebody. On the 6th level, for instance, these drifts are straight for about 700 ft., beyond which point they make a wide curve and run off at an angle of 75°. The working-drifts are never vertically above or below those on the next adjacent level. One series of drifts on the 5th level is in ore that extends down to the 6th level as a sort of sag in the lower limit of the orebody. This will be mined from the 7th level, making a 'lift' (referring to the height of the block of ore mined) of 210 ft., the maximum that

will be necessary according to present plans. The timber in the drifts on the 5th level and in the branch raises above will mingle with the ore when this block of ground is being mined. How much trouble will be caused by its presence remains to be seen; doubtless to some extent it will obstruct uniform drawing. The 5th-level drifts were

ft., even though a completely new start could be made, the fact remains that when the present system was adopted it was necessary to make the best use possible of a large number of unsuitably placed drifts. The present plan provides for an 8th and a 9th level, from each of which approximately 3,000,000 tons will be mined. Recent

drill-holes indicate the probability of still deeper ore, but, according to Mr. Larsh, there are not enough data available to determine how much deeper it will be necessary to go in order to mine all the ore.

An interesting detail is illustrated in Fig. 4, which shows a number of special branches devised for recovering blocks of ore around the edges of the main body and in places where the shape of the enriched part of the deposit is irregular. Experience has proved that a steep angle made by the successive branches from the same raise is to be avoided. It seems that the caved material is likely to carry the timbers of the upper fingers down to the lower draw-points, with dire results so far as the successful drawing of the ore is

run in 1908 and 1909, before any definite conclusion had been reached as to the method of mining to be used, further than that some system of caving must necessarily be devised. If the work were to be done over, in the light of present knowledge of the orebody and of the method of mining, the 5th level would not be opened as it was. In-

concerned. Where the lower boundary of a block of ore is particularly steep a compromise is made as in Fig. 4, where some of the ore is sacrificed and some waste is taken. These diagrams are used by the miners under-

FIG. 4. SPECIAL BRANCHES

stead the entire system of haulage-ways would be arranged to provide for the mining of every part of the orebody in single lifts, the maximum thickness, 310 ft., being ideal for removal of the ore by the branch-raise method. Although the shape of the deposit is such that the average lift would necessarily be much less than 300

ground to point their raises as well as by the stope-engineers for their office-work.

The air-drills used in drifting are Ingersoll-Rand '18a' and '248' water-Leyners and Waugh Turbros; in raising, Waugh '16-V' stopers and B. C. R. W. 430 Jackhammers are both used; for sinking, a water-drill, No. 50 Waugh

Clipper, has preference. Hercules explosives are used exclusively, 95% of the total being 30% dynamite and the remainder 40%.

Table No. 1 summarizes the results of development and stopping operations during the year 1920. On account of the softness of the ore, drilling is an item of less relative importance than usual. The principal indexes to efficient work are the tons mined per pound of powder, the tons mined per board-foot of timber, and the tons mined per man-shift.

HAULAGE. The Star Pointer shaft, through which the hoisting is done, is 200 ft. west of the scene of actual mining. The position of this shaft was determined by the contour of the surrounding hills, which prevented the convenient extension of the standard-gauge railroad tracks to a point nearer the orebody. Long straight cross-cuts serve for motor-haulage from the drifts to the ore-pockets at the shaft. The cross-cuts are timbered with drift-sets consisting of 12 by 12-in. posts and 12 by 14-in. caps. An additional short false set with an 8 by 8-in. cap supports the lagging as shown in Fig. 5.

An interesting detail is the 'laced' lagging used on the sides of the cross-cuts. Short blocks of 2 by 6-in. wood are spiked to the sides of the posts with a six-inch interval between. They project three inches behind the post and thus support horizontal side-lagging made of 2 by 6-in. material, at the same time keeping the pieces spaced after the fashion of a rail-fence. The spaces are then filled with short thin strips placed vertically. These strips prevent slaked rock from continually dropping off, and in so doing keep the cross-cut clean; at the same time effecting appreciable economy in the cost of timber for lagging. The height of the drifts is 7 ft. 4 in. in the clear; they are 6 ft. 6 in. wide at the top, and 9 ft. at the bottom; the track is of 2 ft. 6 in. gauge with 40-lb. rails. The grade is $\frac{1}{2}$ of 1% in favor of the loaded trains, giving, theoretically, the same traction whether the motor is outward bound with a load, or returning from the station with a train of empty cars.

The equipment comprises eight 10-ton trolley-locomotives. Four are equipped with two 30-hp. Westinghouse, Class 59 motors; each of the others is provided with two 45-hp. General Electric motors, all with series-parallel type controllers operating on a 250-v. D. C.

line. All the locomotives are provided with Westinghouse D-4 mine-trolleys No. 1800; the General Electric motor-armatures are equipped with special ball-bearings, whereas the others have the usual babbitted bearings.

Tracks are maintained in first-class condition and the locomotives pull trains of 18 to 20 cars regularly. These cars are built entirely of steel with a capacity of 88 cu. ft.; they have gabled bottoms, and dump from both sides. They are provided with coiled springs over the journals, and on the couplers. It has been found that these refinements in construction have added materially to the life of the cars and to the efficiency of operation.

The accompanying figures, Table II, summarize the motor-haulage during the year 1920.

TABLE II
Ruth Mine. Summary of Motor-Haulage During the Year 1920

Tons of ore trammed.....	818,791.0
Tons of waste trammed.....	33,335.0
Total tons of material trammed.....	852,185.0
Total train-trips.....	13,630.0
Tons of ore trammed per train-trip.....	60.1
Man-shifts on operation.....	6,924.7
Man-shifts on track-repairs.....	1,528.7
Tons of material trammed per man-shift (operation).....	123.0
Tons of material trammed per man-shift (track-repairs).....	557.5
Total man-shifts on tramping.....	9,754.2
Tons of material trammed per total man-shift on tram.....	87.4
Motor-shifts.....	1,666.0
Tons per motor-shift.....	511.0
Average length of tram in feet.....	2,850.0

HOISTING. At the present time all loading in the shaft is done from the skip-chute below the 7th level, although most of the ore comes from the 5th and 6th levels. On account of the short lift between levels, the construction of skip-chutes for each level was inadvisable as it would have weakened the shaft seriously. Accordingly the ore-pocket below the 6th level was built with its centre 35 ft. behind the centre of the shaft and 12 ft. behind the centre of the pocket, or skip-chute, below the 7th level. The bin proper is 10 by 20 ft. and 17 ft. deep inside dimensions, with a hoppers bottom funneling into a cribbed raise 4 by 6 ft. in cross-section on an incline of 55°. A gate, operated by an air-cylinder, controls the flow of the ore into the 7th-level skip-pocket. The cylinder is below the bottom of the spout and the gate cuts off the stream of ore from beneath instead of from above. This detail of design is found generally in the mine; even where the cylinder must be above the chute; in that event the gate is operated in the same manner by the use of a yoke that spans the spout.

Below the 7th-level skip-chute is a measuring-pocket designed to hold six tons, the capacity of the skips. There are, in fact, two measuring-pockets, one for each of the two skip-compartments in the shaft. The distance from the top of the 8th-level station to the lip of the loading-chute is about 5 feet.

Ore from the 5th level passes to the 7th by way of the ore-pocket on the 6th, so that all of the loading is done through the measuring-bin at the lower level. The whole arrangement, shown in Fig. 6, works smoothly and efficiently and 6000 tons per day could be loaded easily. During 1918 approximately 3650 tons per day was hoisted but this did not begin to measure the capacity of the loading or hoisting arrangements. It will be observed that a somewhat similar arrangement on the opposite side of the shaft serves to collect the waste from the sixth level in the pocket below the seventh from which it may be loaded into the skip.

In addition to two compartments for the 6-ton steel skips, the shaft has two ladder-ways and a cage-compartment, used for hoisting and lowering men and supplies. The three larger divisions are 5 ft. 6 in. by 6 ft. in the clear. Ordinary shaft-sets, the principal members being of 12 by 12 timber, are spaced at 4-ft. centres.

The steel head-frame was erected in 1908 by the Minneapolis Steel & Machinery Co. It is 77 ft. high. Recently the ordinary cast-iron sheaves have been replaced with those of the bicycle type mounted on a shaft of 8-in. diameter. The vibration at the hub is decreased and the sheave-shaft lasts longer.

The ore-bin with a capacity of 2000 tons spans the railroad track, which parallels its length, as may be seen in the accompanying illustration. The original plan provided for sizing the ore prior to shipment to the concentrator at McGill; with this end in view a grizzly with bars spaced one inch was placed at the top of the head-frame. The skips dumped on this grizzly; the fine material was delivered to the central compartments of the bin, while the coarser portion followed inclined chutes to either end of the bin. The scheme was to load the fine product in separate cars and avoid sending it through the coarse-crushing plant at McGill. This idea was abandoned, but the grizzly serves a useful purpose in that the oversize material requires considerably less grade than would run-of-mine ore. As a consequence the ore can be distributed to the extreme ends of the exceptionally long bin, by gravity, without mechanical assistance.

In June 1918 a new electric hoist was installed to operate the skips. This is a double-drum heavy-duty geared machine made by the Nordberg company. Six-ton skips are pulled, in or out of balance, with a rope-speed of 800 ft. per minute. A 1½-in. 6-strand 19-wire plow-steel Roebling cable is employed.

The hoist is connected through herringbone gears to a 400-hp. Westinghouse phase-wound motor operating on a three-phase 60-cycle 550-volt line. Clutches and brakes are controlled by oil, and Welsh safety-stops for over-wind and over-speed are provided.

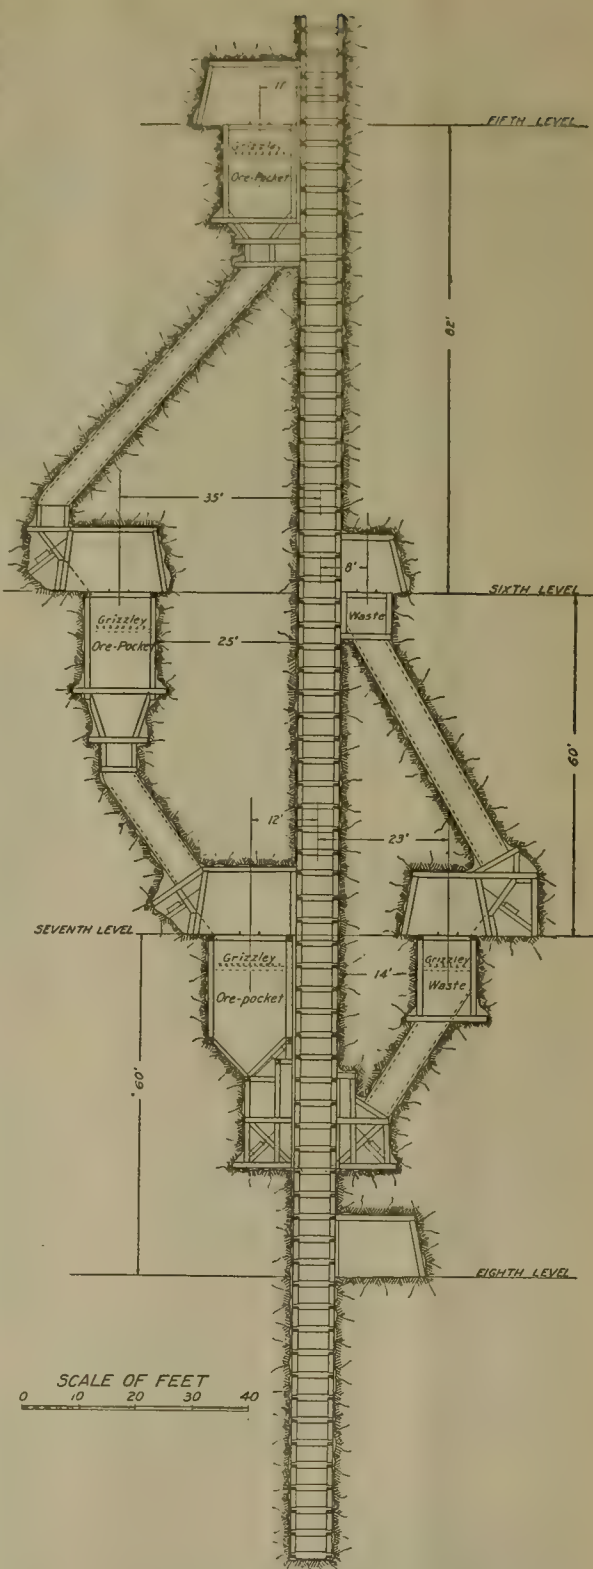

FIG. 6. ARRANGEMENT OF ORE-POCKETS AT THE STAR POINTER SHAFT

A summary of hoisting operations for the year 1920 follows:

TABLE III

Ruth Mine. Summary of Hoisting Operations During 1920

Skips of ore hoisted	137,871.0
Skips of waste hoisted	5,687.0
Cages of timber handled	3,179.0
Cases of men handled	10,921.0
Total dry tons of ore hoisted	818,791.0
Total tons of waste hoisted	33,335.0
Total tons of material hoisted	852,185.0
Total man-shifts	6,609.8
Tons of material hoisted per man-shift	128.9
Average number of dry tons per skip	5.94
Average distance hoisted, feet	610.0
Average time of skip in minutes	1.26

Two machines that give especially good satisfaction are the compressors. Over a period of one month they produced at the rate of 1000 cu. ft. of air per minute with an input of 2.04 kw-hr. as compared with the manufacturer's guarantee of 2.25 kw-hr. This particular record is exceptional, but the performance is consistently good. The compressors are manufactured by the Ingersoll-Rand Co.; they are type P.R.E. 2-stage machines, fitted with Ingersoll-Roegler valves and rated to compress 3200 cu. ft. per minute to 90-lb. pressure. Each is direct-connected to a 550-hp. Westinghouse synchronous motor, and in conjunction with each machine is an A-33 clear-ance regulator.

The appended figures show in a general way the results of the operations during the year 1920:

TABLE IV

Ruth Mine. Summary of All Mining Operations During the Year 1920

	Porphyry mining	7th-level square-set mining	Total Ruth mine
Tons of ore hoisted	817,509	1,282	818,791
Number of days of operation	362	32	362
Average number of tons of ore hoisted per day	2,257	40.1	2,262
Average number of man-shifts per day, underground	183	13	184
Average number of tons of ore hoisted per man-shift, underground	12.30	3.09	12.27
*Average number of man-shifts per day	223	18.6	224.2
†Average number of tons of ore hoisted per man-shift	10.10	2.13	10.05
Average number of total man-shifts per day charged to Ruth mine	250	20.6	251.4
Average number of tons of ore hoisted per total man-shift	9.04	1.93	8.99
Total board-feet of timber used	3,105,451	30,433	3,135,884
Average number of tons of ore hoisted per 1000 bd.-ft. of timber	263	42.1	261
Total number of kilowatt-hours of elec- tric energy consumed	3,692,239	4,567	3,696,676
Average number of tons of ore hoisted per kilowatt-hour	0.221	0.281	0.221
Average number of kilowatt-hours per ton of ore hoisted	3.69	3.56	3.69
Total thousands of cubic feet of air consumed	824,439	256	824,695
Average number of tons of ore hoisted per thousands of cubic feet of air	0.98	5.00	0.98
Average number of thousands of cubic feet of air per ton of ore hoisted	1.03	0.20	0.98

*Exclusive of labor on deferred construction at the Ruth mine.

†Total man-shifts include labor of all descriptions charged to the Ruth mine.

It will be noted that in Table IV, 1282 tons of ore is

recorded as having been mined by square-set methods on the 7th level. This is from a deposit of high-grade ore first opened in the summer of 1920, at a point where the main cross-cut from the Star Pointer shaft first cut the ore-zone. Much of the ore assayed from 7 to 10% copper; it is a product of 'secondary' enrichment. It is possible that similar lenticular masses will be found at other points on the periphery of the central core formed by the main orebody, but the deposit is recognized to be only a comparatively small isolated bunch of ore in connection with which no great geologic or economic significance can be attached.

Table V is a recapitulation of the operating cost from the time production commenced in 1915 up to the present time. As appears from the items listed, the deferred cost of development, including the driving of haulage-drifts, is not part of mining expense. The figures do represent, however, every direct and indirect cost incurred from the time the branch raises are started until the ore is delivered to the storage-bins at the surface. Under the head 'Miscellaneous' are included the items of depreciation, depletion, and taxes of every kind. The incidence of Federal taxes is apparent in the large increase in this last item for 1917 and 1918 and in the decline during the following years when profits decreased. The fact that the direct operating cost for 1919 and 1920, on a greatly decreased tonnage, was no greater than in 1918 is accounted for by the improvement in the individual efficiency of the miners and also as a result of economies that have been effected by further systematization of operations.

It is interesting to revert to the early estimates of J. Parke Channing, Henry Krumb, and other engineers who agreed that \$1.50 per ton was a fair estimate of the probable cost for mining the Ruth ore. More significant still is the comparison of the cost at Ruth with that reported at two other mines where the ore deposits are somewhat similar. The mining cost at Ruth for 1919 was \$1.35 per ton including deferred charges for development and equipment. For the same year the cost of underground mining at the Ray Consolidated mine exclusive of sundry special charges for extracting high-grade ore by square-set methods is given as \$1.60; at the neighboring mine of the Miami Copper Company the cost for 1919 according to the annual report was \$1.540. Differences in the orebodies, in the working conditions, and in the methods of accounting, of course, vitiate the value of any direct comparison, but the records speak well for the work being done by the Nevada Consolidated company.

TABLE V

Ruth Mine. Per-Ton Cost of Producing Ore During the Period 1915 to 1920

	1915	1916	1917	1918	1919	1920
Tons produced	86,029	591,545	991,830	1,316,144	718,142	816,605
Branch raises and sub-levels	\$	\$0.0193	\$0.0972	\$0.2800	\$0.2344	\$0.2412
Under-cutting and caving	0.6443	0.3931	0.1982	0.1829	0.1300	0.1794
Tramming expense	0.1386	0.1473	0.0972	0.0867	0.0915	0.0794
Hoisting expense	0.0877	0.0579	0.0423	0.0564	0.0665	0.0615
General underground upkeep	0.3263	0.2902	0.2334	0.2249	0.2846	0.2436
General mine expense	0.0715	0.0466	0.0384	0.0444	0.0628	0.0708
Miscellaneous	0.1038	0.2477	0.3184	0.4102	0.1798	0.1391
Total	\$1.3722	\$1.2021	\$1.0251	\$1.2855	\$1.0496	\$1.0160

amounts of bromide and chloride of silver. A large amount of the quartz present in the ore is in the form of small crystals and fragments that are cemented by the lime and intermixed with calcite; consequently, the ore shatters easily. More than 60% of the Arizona mine ore, as it comes from underground, will pass a four-mesh screen. The remaining 40% is reduced in an old type of jaw-crusher by the mine crew during part of the day shift, so that all the ore delivered to the bin is sufficiently fine for stamping.

The capacity of the battery bin is 80 tons. From there the ore is fed to five 1050-lb. stamps by a Challenge feeder. The battery discharge is elevated with a small bucket-elevator to a 48-in. Akins classifier, in closed circuit with a 4 by 9-ft. tube-mill. The classifier overflow is delivered by a 2-in. centrifugal slime-pump to a Dorr thickener, 20 ft. in diameter and 11½ ft. high. The underflow, containing from 50 to 60% of solids, flows by

circulate the pulp of thickener No. 3 by continually taking it from the bottom and discharging it into the receiving well. This arrangement makes possible the accumulation and storage of pulp in the thickener when the filter is idle. Thickener No. 3 is similar to thickener No. 2. The pulp is again washed by the addition of three parts of barren solution to one part of solids. The overflow goes to thickener No. 2 and the underflow to an Oliver filter.

The filter is 12 by 8 ft. and is operated for part of the time only. The filter-cake is washed with sprays of barren solution and water. The wash-water is used as cooling water for the compressor, where it becomes warm. The washed cake is carried outside the mill by a 16-in. belt-conveyor. Vacuum is maintained with a 3-in. rotary pump. The clarifier tank is 16 by 5 ft. The clarifying medium consists of six home-made leaves, which are simple in design, easy to build, cheap, and satisfactory. The

leaves are connected to a 3-in. Roots rotary vacuum pump; the clarified solution is delivered to a 12 by 10-ft. tank. From this tank the rich solution flows by gravity to four 9-compartment zinc-boxes. The compartments are 20 by 22 by 24 in. and are made of sheet-iron. Nearly a ton of zinc shavings is required to fill the boxes, but at the present time only seven compartments of each box, two-thirds full, are needed. The solution from the zinc-boxes discharges into a rectangular box, 12 by 12 in. by 4 ft., and then through a vertical

FIG. 2. VACUUM-LEAF IN CLARIFIER

gravity to a Dorr agitator, which is 18 ft. in diameter and 15 ft. high. Part of the overflow is sent to the clarifier and part to the battery storage-tank. The pulp in the agitator is diluted, with barren solution, to a consistence of 40% solids, the strength of the solution being maintained at 4 lb. per ton by the addition of fresh cyanide. The solid cyanide is placed in a basket and dissolved by the stream of solution used to reduce the specific gravity of the pulp. Every two hours, a part of the pulp from the agitator is transferred by gravity to No. 2 thickener, which is 18 ft. in diameter and 8 ft. high. The pulp from this is mixed with the overflow from No. 3 thickener and the Oliver filtrate. When the filter is idle, an equal amount of barren solution is substituted. The dilution in this thickener is four to one. The overflow is the richest solution in the mill and is sent to the clarifier.

The underflow from thickener No. 2 is pumped into thickener No. 3 with a 2-in. Dorco diaphragm pump; the piping is arranged so that it can either deliver the underflow from thickener No. 2 to thickener No. 3, or else can

weir into a 16 by 5-ft. sump-tank. A triplex-plunger pump delivers the solution from the tank to a 15 by 8-ft. barren-solution tank at the head of the mill.

The amount of ore treated per day is limited by the capacity of the tube-mill, which is 20 tons at the present time. The physical state of the ore is such that 50% slimes easily, whereas the other half is difficult to reduce beyond 60 mesh. The management has under consideration the separation of the slimes from the sands, and the treatment of the latter by leaching, in a separate plant. In case the leaching plant is erected, a ball- or rod-mill will be added to the crushing department. The present slime plant is large enough to handle at least 40 tons of slime per day. The ore settles rapidly, 3 sq. ft. of settling area per ton of ore being sufficient. The consumption of cyanide is 2.7 lb.; lime, 1.5 lb.; and lead acetate, 0.3 lb., per ton of ore. By careful proportioning of the amounts of cyanide, lime, and lead acetate, the oil in the ore is rendered comparatively harmless. Flotation before cyanidation is unnecessary.

The Ways of the London Silver Market

By Robert P. Skinner, U. S. Consul General in London

*The London silver market is the greatest in the world. Its importance is so firmly established as to have given rise to the impression that the brokers by whom the daily changes are recorded operate under a patent from the Crown, all others being prohibited from participating in these transactions.

The suggestion is made that there is no actual open market either in London or in New York for trading in silver; that is to say, "there is no competitive bidding among brokers and no market place open to all interested, and, further, there are no opening and closing quotations". The main suggestion that the London silver market is in the hands of four particular concerns is undoubtedly true, but it is not a fact that this practical monopoly has been legalized by the Government in any manner, and there is no reason in law why anyone who wishes to do so should not set up as a broker in silver in London if he can find clients willing to employ his services.

For several generations four firms have formed the London silver market, namely, Mocatta & Goldsmid, Sharpe & Wilkins, Pixley & Abell, and Samuel Montagu & Co.

Mocatta & Goldsmid started business in 1695 as bullion brokers on behalf of the Bank of England, and had their office in the present Bank of England. They were practically the bullion department of the bank, and bullion in those days represented coin, bars being seldom seen. After about 125 years of this monopoly a large constituent of the firm started one of the firm's clerks in business outside the Bank of England; this undertaking developed into the firm of Sharpe & Wilkins. At a later date Pixley & Abell appeared in the same business, and more recently, somewhere about 30 or 35 years ago, Samuel Montagu & Co. began to include bullion transactions along with the details of their banking business, which they had carried on for a long time.

It is said on behalf of these four firms that their position is due to their own high standing and the confidence arising from methods and practices adopted to protect the interests of buyer and seller alike.

What is called 'fixing' the price of silver is a London operation which controls the price of the metal in several important financial centres throughout the world. The official quotations are cabled abroad by each of the four firms named to their foreign clients. The great bulk of the daily business transacted is based upon the price, which is determined by 1:45 p.m. every day in the week (on Saturday the hour is 11:45 a.m.), when the representatives of the respective firms meet at the office of one of their number.

Each of the four brokers is permitted to disclose the excess of his own position as a buyer or seller at a given price while preserving the anonymity of his client. It will thus be seen that while one of the firms may do an enormous business on any one day, the difference between purchases and sales may be extremely small; and carrying this idea through the four firms it will be seen that while the total volume of trade may be enormous the amount changing hands between the four concerns may be trifling.

In an interesting work entitled 'Silver, its history and romance', by Benjamin White, the following paragraphs on the price-fixing method appear:

"The method of fixing the price is very simple. The first step is usually to ascertain if there is occasion to alter the price of the day before. If supplies prove insufficient to satisfy buying orders higher prices are suggested until the offerings balance the demand. Should offerings at the preceding day's price exceed the amount of buying orders, the price is lowered until equipoise is obtained. Usually a number of orders at different limits have been left in hand by clients, to buy or sell; with the assistance of these orders the price can be adjusted to a nicety. By this method of fixing the quotation the scale is evenly held between the buyer and the seller for whom the brokers act.

"As a rule, two prices are agreed upon at 'fixing', one for a cash delivery, which implies delivery within seven days—at the option of the seller—and the other for delivery in two months time; that is to say, exactly after two calendar months interval. A period of two months is selected because it is found the most convenient interval at which smelters can undertake to deliver the silver which they have purchased in the form of ore."

From a high authority in the London financial world the writer has obtained some further interesting details about the technique of the business:

"The statement you quote that the brokers meet daily to 'fix between themselves the price for which they will buy and sell for that day' is not quite accurate. The fact is that the brokers do not buy and sell; the brokers 'broke' on commission; their clients buy and sell. Their clients are chiefly exchange banks interested in many parts of the world, but so far as silver is concerned chiefly in India and China.

"China and India have each of them a rate of exchange on England. These rates of exchange vary almost daily, and each rate of exchange has an equivalent in silver bullion. For example, if the rate of exchange in Shanghai is 9s. per Chinese tael, silver bullion is worth a very high figure per ounce; if exchange is 4s. 6d., the price that they will pay for silver bullion is only half the

*'Commerce Reports', April 5, 1921.

former price. Both these rates of exchange have been current within the last 12 months, hence the wide fluctuation in the price of silver without the slightest manipulation on the part of the brokers. The banks know what rates for silver will pay them and what will not pay them, and they give their orders accordingly; that is, usually with limits—say: 'Buy [or sell] on our account 100,000 ounces today at 42d., or perhaps a fraction higher, but not above 42½d.'

"The fact is that the China and India rates of exchange on London dominate the silver market, hence the fact that the London market dominates the American price of silver. Now, if the London price is 50d. and the rate of exchange on New York is \$4.86, the market price is a very different figure if the rate of exchange moves to \$3.50 per English pound. This provides you with two variables—first, the Chinese or Indian rate on England and then the London rate on New York; and all the mysteries of variations in the price of silver come down to these two factors, so that the mysteries are simplicity itself. They are simply buying and selling by responsible banks through responsible brokers. Silver is a commodity and travels up and down in response to supply and demand and cannot be made to follow the wishes of producers any more than wheat or cotton can be kept within certain bounds."

Answering a question on the subject of competition from other silver markets this same authority said:

"Outside competition would hardly stand a chance within the next 50 years, if that. First of all, a broker requires a clientele on both sides of the ledger; for instance, at present the large supplies of Continental silver resulting from the melting down of Continental currencies come to the brokers through their old Continental customers, collected together into their books through the experience of years and years. During the last nine months these supplies of Continental silver have been very much larger than supplies of American silver—in fact, the market has been, to a large extent, independent of American supplies—and we believe that there were times when America sold nothing here, but, instead, sold it for delivery in San Francisco to exchange banks (representatives of the exchange banks here). However, they have been able to sell there only at the equivalent of the rate arranged in London on the day of their sales in San Francisco or New York, or close thereto, so that London has still dominated the American market.

"At present it looks as though the Continent of Europe can go on selling indefinitely, largely owing to the fact that Continental rates of exchange are so high here as to give the sellers a wonderful return for their currencies. For instance, at 260 marks per pound on Berlin, Berlin is reaping in paper, 13 times its normal return on silver. In addition, China and India have absorbed such abnormally large quantities of silver while the prices of produce were high that it looks hardly possible for either of them to continue absorbing at anything like the same pace; in fact, there is quite a possibility, if not a probability, that with trade in its present languishing condi-

tion the world over, large disorgagements of silver from those quarters might take place.

"You will appreciate that bullion brokers have to be aware of, and in daily touch with, all these factors, and also that it is not a business which can be taken hold of at five minutes notice and proceeded with in the absence of long and inherited experience."

Undoubtedly the four firms in charge of the London market exercise an enormous power, which extends to every part of the world and particularly to the United States, India, and China; but inquiry fails to disclose a single definite complaint that they artificially manipulate the market, although numerous observers recognize that they are potentially able to do so.

As already stated, there are no governmental measures of special character which apply to this business. However, a bill is now pending in Parliament which provides that it shall be unlawful for any person except under Treasury license to melt down, break up, or use otherwise than as currency any gold or silver coin that is for the time being current in the United Kingdom or any foreign country, and that likewise includes silver coin and gold or silver bullion among the articles the customs authorities may prohibit from exportation.

An agreement was made in 1919 between the Dominion Department of the Interior and the Hydro-Electric Commission of Ontario, whereby the Dominion Water Power Branch became responsible for all basic investigation respecting water resources, and the Province undertook detailed investigation and construction, states a consular report. A special Federal bureau was formed to deal with this work. During the past year stream measurements and investigations have been largely extended, and an inventory and analysis of developed and undeveloped power and storage resources is now being prepared. Included in this work are the studies of the St. Lawrence river and the regulation of the Lake of the Woods for storage purposes. The progress in actual construction includes the installation of two new units of 20,000 hp. each in the plant owned by the Ontario Power Co. at Niagara and the completion of a 3500-hp. plant at High Falls, near Perth. Development at Queenston on the Niagara was continued, and it is expected that power will be available from this plant in September; the initial installation is of five 60,000-hp. units, with an ultimate capacity of 540,000 hp. Development on the Nipigon, to supply the Port Arthur and Fort William districts, with an initial installation of 25,000 hp., and an ultimate capacity of 75,000 hp. was continued, and power is now being supplied from the first unit. Construction was begun on a 10,000-hp. plant at Ranneys Falls, near Campbellford, to supply the central Ontario system. The total capacity of plants now owned by the Hydro-Electric Power Commission is given as over 1,000,000 hp. Private developments included the completion of a dam for a 15,000-hp. plant on Spanish river at Algoma for the International Nickel Co. In all there was a total of about 500,000 hp. under construction in Ontario in 1920.

REVIEW OF MINING

UTAH MINING COMPANIES RESIST ATTEMPT ON PART OF A. S. & R. CO. TO ABROGATE SMELTER CONTRACTS

The Silver King Coalition and the Daly-West mining companies, whose mines are at Park City, have decided to resist all attempts of the American Smelting & Refining Co. to abrogate their unexpired contracts relating to charges for the treatment of ores. Notification was recently received from the American Smelting & Refining Co. stating that after May 15 no ores would be accepted by it under the rates provided for under the old contracts, notwithstanding the fact that these agreements had several years to run.

With this notification a new schedule of rates was submitted by the smelting company for approval. The reason for refusing to accept the ores under the old contracts was that the charges stipulated therein were unprofitable under present operating costs.

Although but two companies at present are directly affected by the proposed abrogation of unexpired contracts, Utah mine operators are watching closely developments bound to arise out of the controversy. Feeling in mining circles is running high, for it is felt that if the American Smelting & Refining Co. can abrogate its contracts when they are deemed unsatisfactory and live up to them only when they are favorable, it will be futile in the future to make an agreement providing for a stipulated smelting-charge over a term of years.

Many mining operators feel that if the smelting company is able to impose arbitrarily smelting rates favorable alone to its own interests, a blow will have been struck at the intermountain metal industry from which it will be slow to recover. Out of this conflict, many mining men believe that there will grow a co-operative movement whereby producers will be enabled to market their own ores. As a matter of fact, the practicability of mining companies owning and operating a co-operative smelter is being strongly discussed.

Regarding the controversy, W. Mont Ferry, managing director of the Silver King Coalition Mines Co., made the following statement: "The contract held by the King Coalition Mines Co. was entered into January 1, 1914, for a period of ten years. This contract provided for a fixed rate for the first five years and for a lessened charge during the second five years, beginning January 1, 1919.

"Under the contract, the American Smelting & Refining Co. agrees to take all crude ore and concentrates up to a limit, as yet never approached, and to make certain stipulated charges upon receipt f.o.b. Park City. Now the smelting company proposes to revoke this contract because under its terms treatment of Silver King Coalition Mines ore is unprofitable.

"Furthermore, we have been informed by the smelting company that it is only the agent of the miner, his middleman, and that no loss of income resulting from an increase in the cost of operation will be sustained by it. In other words, the smelting company announces that, notwithstanding any contract it may make, the miner must be prepared to meet any increase in reduction costs by an advanced smelting charge. We fully intend to hold the smelting company strictly to the letter of the contract.

"Even if the contract is unfavorable to the American Smelting & Refining Co., this is hardly a justifiable reason for attempting to disregard it and arbitrarily impose rates which are on the average 75% higher than those in force at present.

"For twenty-eight years the Silver King Coalition Mines Co. has shipped its ores to the American Smelting & Refining Co. Though the terms of past contracts under which ore was sold to the smelting company have not been always favorable to the best interests of the mine, they were lived up to."

George W. Lambourne, president and general manager of the Daly-West Mining Co., says that his company would take the same stand as that of the Silver King Coalition company. He said that he had "no intention of complying with the unjust demands of the smelting company", and that his company would insist that the terms of the contract, which has about four years to run yet, should be fulfilled.

J. M. Bidwell, general manager for the A. S. & R. Co. in Utah, made a statement from which the following is extracted: "Each contract contains a provision that when and if conditions arise in the smelting business beyond the control of the company which render the smelting of their ores unprofitable at the contract rates, or make it a disability or serious hardship to receive and smelt them, then the contracts may be suspended.

"The contracts also provide that in case market or mining conditions make it a serious hardship for the mining companies to ship ores, they shall not be obligated to ship them. In other words, if the cost of mining became excessively high, or the metal prices excessively low, and the mining companies cannot ship at a profit under the contract, they are not obligated to ship their ores.

"A contract to be binding upon both parties must be mutual, and if the mine owner is not required to ship, if in his judgment he cannot do so to advantage, the same condition should apply to the smelting company; and if conditions should arise making the handling of the ore by the smelting company a serious hardship they should have the same right of either asking the mining company to discontinue shipments or to ask them to pay more money to smelt their ores.

"The smelting company has notified these two mining companies that their ores will be received if they will pay the actual cost of smelting them figured without one cent of profit to the smelter; and they have been advised that each month the smelting company will figure its cost and when these costs become lower than at present the mining companies will be given the benefit of such reductions.

"We feel that these reductions will be material and will come about in the near future. The smelting company is doing everything possible to bring about lower costs, all of which shall inure to the benefit of the mines."

Regarding the so-called disability clause, Mr. Ferry contradicts the statement of the A. S. & R. officials. He quotes the clause verbatim as follows: "In case of acts of nature, strikes of any kind, affecting the operations of the contracting parties, fires, floods, shortage of cars, financial crises, war or insurrections, or any cause whatsoever, which, being beyond the control of the contracting parties or either of

them, shall make it a disability on the part of the mining company to ship the product herein contracted, or for the smelting company to receive, purchase and treat such product, the parties hereto shall be relieved of all responsibility or claim for damage for failure to ship or receive the product; but shipments and receipts shall be resumed as soon as the disabling cause is removed, and the period of such interruption or interruptions shall be added to the time provided for in this contract."

THE STRIKE AT TONOPAH

The strike at Tonopah, at the time of our going to press, had become more serious, with both sides apparently resolved on a finish fight. The Tonopah-Belmont Development Co., the largest operator in the district, has discharged all salaried employees, including shift-bosses, and several other companies were reported to be planning like action. An attempt last week to break the strike by importing forty-five strikebreakers from California failed when the men were persuaded to leave the camp by the strikers. The lower workings of the Belmont, Tonopah-Extension, and other mines are filling with water, and, according to officials, several months will be required to place these workings in shape for mining even should the strike speedily terminate. Large numbers of men are commencing to leave for other points and the business outlook is gloomy.

Operations remain normal at Klondyke, but it is unlikely that the lessees can work much longer without an outlet for their ore, as previous to the strike all Klondyke ore was treated by mills at Tonopah and Millers. The companies that continue to pay the old scale make more difficult the position of the operators who have announced a wage-cut. Practically all companies with the exception of the Tonopah Divide are working at Divide under the old scale. The move to cut wages is said to have been made by the Eastern interests in the big companies and these interests would have more sympathy in their attempt if the move had not been so sudden, according to the talk heard among mining men throughout the State.

HOMESTAKE PAYS DIVIDEND

The Homestake Mining Co., whose mines are at Lead, South Dakota, has declared a dividend of 25c. per share. This is the first dividend that the company has paid since September 25, 1919. The total dividends amount to slightly more than \$42,000,000.

ARIZONA

Bisbee.—The Calumet & Arizona and Copper Queen mining companies are preparing to do development work in the White Tailed Deer district. The Calumet & Arizona is installing a hoist at the Cole No. 3 shaft and will start drifting from the lower levels. The Copper Queen company will work from the White Tailed Deer shaft.

The Calumet & Arizona company has stopped sinking operations at the Campbell shaft on account of the flow of water which has increased to such an extent that it can no longer be bailed. The shaft is now below the 1700-ft. level. It has been concreted 698 ft. from the collar, and work of concreting the rest of the way has been commenced.

The drift from the 1800-ft. level of the Junction that will drain the Campbell shaft is now about 200 ft. from the shaft. As the Junction is the pumping shaft for all the C. & A. mines it will be necessary to maintain the bottom of the Junction at a lower level than the other shafts. If the Campbell shaft is to be sunk much farther, it will be necessary first to sink the Junction.

Pulling of the pumps at the Denn mine has had no appreciable effect on pumping at the Junction. The Denn mine

has filled up to about 33 ft. from the 1600-ft. level, on which is the connection with the Junction.

Jerome.—The United Verde Extension produced 3,092,746 lb. of copper in April, compared with 2,951,390 lb. in March, and 3,349,942 in February.

Kingman.—Work is progressing on the Nancy Lee property, situated in Secret Pass about four miles from the Katherine mine. The Nancy Lee carries a vein of lime-quartz the outcrop of which assays from \$2 to \$10 per ton. A cross-cut adit has been driven a length of 100 ft. for the purpose of tapping the vein at depth and will reach its objective about 50 ft. in advance of the present heading. —At the Sunbeam property, Ed. Chaffee, superintendent, is preparing to install a 40-hp. hoist, a 350-cu. ft. air-compressor, and a 75-hp. gas-engine. Mr. Chaffee negotiated the sale of the Sunbeam to W. J. Loring and has been supplied with the funds necessary to develop the property. The work will include the sinking of a double-compartment shaft to a depth of 500 ft. —On the adjoining Adams group, machinery is being installed. N. I. D'Arcy and E. H. Newland are backing the venture.

Tombstone.—An arrangement has been perfected by John H. Davis, superintendent of the Bunker Hill Mines Co., whereby 1000 tons of lead-silver ore from this district will be shipped to the smelter at El Paso. The ore is desired partly for its fluxing properties, and a low treatment-rate has accordingly been made. The Lucky Cuss and Oregon mines will probably supply most of the ore.

Winkelman.—The report of the discovery of \$20 gold ore on several claims in Gold canyon north of the Gila river between Kelvin and Winkelman has caused a small 'rush' into the district. The original discovery was made on the Victor No. 1 claim belonging to Riggins and Schuyler. About 30 claims have been located to date.

Winslow.—It is reported that the Colorado Fuel & Iron Co. has taken a lease on a large acreage of iron-bearing ground on the Apache Indian Reservation 60 miles south of Winslow. It is said that there is a large tonnage of known ore that will average 55% iron. Drilling operations are to be commenced to further prove the area.

CALIFORNIA

Forest City.—The Kate Hardy Mining Co. is erecting a new 10-stamp mill. Following the practice at the Empire and North Star mines, at Grass Valley, 1650-lb. stamps are being used in preference to lighter ones. High-grade equipment is being used throughout.

Grass Valley.—The Alta Combination Mines Co., under the direction of H. L. Ostrander, has extended the adit at the Baltic property to a length of 1000 ft. It is expected to reach the Alta Hill gravel channel at a point about 750 ft. farther on. A new reservoir will supply water for power purposes under a head of 212 ft. The Alta California Co. is said to have entered the gravel channel.

Redding.—The Mountain Copper Co.'s output at the Hor-net mine has been cut down to 4000 tons per month, that being all that the General Chemical Co. at Bay Point requires. The Chemical company took 15,000 tons in February, 10,000 tons in March, 8000 tons in April, and now only 4000 tons is wanted in May. The decrease is due to the falling-off in the demand for sulphuric acid and fertilizers. The company has been obliged to reduce its force from 150 to 100 men.

Shoshone.—The Associated Oil Co., the Pacific Coast Borax Co., and W. S. Bayliss are each developing, or prospecting for, deposits of fuller's earth. —Preparations are being made to treat with cyanide the old dumps at the Confidence mine. —The Silver Valley Development Co. has sunk a 250-ft. shaft on its claim 25 miles north of here. In-

dications are favorable for the development of silver-lead ore.—J. J. Jarvis, of New York, is developing the Silver Rule and Blackwater properties in the hope of finding silver-lead ore.

Tecopa.—Lessees are working on the 700-ft. level in the Gunsite claim of the Tecopa Consolidated and the company is doing development work. The Tecopa is a lead-silver mine that is opened or closed according to the price of lead, freight-rates, and smelter-charges.

Tuolumne County.—G. L. Sledge, W. W. Godsmark, O. H. Crane, and other men from Los Angeles have taken over the W. N. Sledge gravel claims four miles east of here. These claims formerly belonged to the Tuolumne Deep Channel Mining Co. and were in litigation for many years. The matter was settled in court a short time ago, the present owners gaining control. The new owners will begin work immediately.

COLORADO

Aspen.—The rich shoot in the Hope tunnel has been proved by drifting to be 55 ft. long; a raise from the tunnel-level has opened a strong body of silver-lead ore in a dark lime, with the richness steadily increasing, according to the recent report of the directors to the stockholders. Roads are clearing and shipments will start this month.

The Anaconda group on Porphyry mountain has been taken over by Salt Lake operators and the Argenta group in the same section by Chicago and Eastern interests. The Aspen Silver-Lead Mines Co. continues development of its Porphyry mountain properties and will be shipping shortly.

Black Hawk.—The Midwest Mining Co. has increased its operating force. The new mill will shortly be completed and large reserves of ore are available. The old plant continues operating and is turning out a good grade of concentrate.—The Silver Mountain Mining Co. has entered a body of smelting-grade ore between the 260 and 200-ft. levels and is prospecting undeveloped territory by cross-cutting.

Cripple Creek.—Extension of the Roosevelt drainage tunnel from its present terminal on the Portland estate to the Vindicator Con. Gold Mining Co.'s No. 2 shaft, a distance of approximately 3000 ft., is under consideration by the Vindicator directorate. The estimated cost is between \$100,000 and \$150,000. Rich ore has recently been found in the Vindicator mine at a depth of 2000 ft., but the cost of raising water is heavy and eats up profits.

The Jo Dandy mine on Raven hill and the Mary Ann adjoining, owned by the mining companies of the same names, have been taken under lease by T. B. Burbridge, of Denver, a director of the Cresson Consolidated Gold Mining Co., whose property the Mary Ann adjoins. A bond has been secured on the Mary Ann. The lease is significant, although Burbridge declares the Cresson company is not interested.

The Jo Dandy was, until closed down about three years ago, a producer of high-grade ore, but the Mary Ann has been inactive and undeveloped since patent issued, except for prospecting by lessees.

Kokomo.—The Mutual Co-operative Mining Co., of Denver, is receiving royalties from shipments from the Silver Queen mine. Five cars were recently settled for by the A. V. smelter at Leadville, and two other cars await settlement. The force has been increased by the lessee, and royalties from shipments, it is estimated, will average \$200 per week.

IDAHO

Coeur d'Alene.—The Bunker Hill & Sullivan company has been commended by Stewart Campbell, State Mine Inspector, for the exceptionally fine condition of its mine and the methods used to prevent accidents. Favorable comment

was made upon the large concrete change-house built near the entrance to the Kellogg tunnel for the convenience of the miners. The change-house is equipped with hot and cold showers, drinking-fountains, lockers, and other conveniences. Precautions against fire in the mine, shops, and buildings by the application of a coat of gunite is also mentioned.

According to official statements of mining companies filed with the Shoshone county assessor, the total production for the Coeur d'Alene region in 1920 was 130,822,570 tons of ore, valued at \$24,804,860, and net profits were \$6,318,855. The largest producer was the Bunker Hill & Sullivan com-

King Incline, Arizona Copper Co., at Metcalf

pany, with 409,986 gross tons of ore. The Morning mine of the Federal Mining & Smelting Co., at Mullan, was second with 314,027 tons, and the Hecla mine at Burke was third with 229,893 tons. The net profits of the different companies were as follows: Bunker Hill & Sullivan, \$2,593,089; Hercules, \$1,147,706; Hecla, \$1,092,602; Federal (Morning mine), \$568,072. The Bunker Hill profits, according to officials, were made during the first six months of 1920, when war prices for metals still prevailed. The company has about 'broken even' since then.

The North Star Mining & Development Co. has extended its tunnel 174 ft. and re-opened and re-timbered 50 ft. of caved tunnel, put in a trestle that cost \$400, added to the equipment a blower for the blacksmith shop, 300 ft. of 10-in air-pipe, a fan, and other improvements.

The recent strike of high-grade gray-copper ore on the

Sterling Silver property is encouraging, according to Harry Morrell, manager. The vein was cut at a depth of 300 ft. from the surface on the lower level of the workings while a cross-cut was being driven to open a vein found on the surface. Three feet of gray-copper ore was opened. Five men are at work and cross-cutting will be continued 350 ft. to cut the vein. The mine is seven miles from Kellogg, and the ore can be hauled to the Bunker Hill & Sullivan smelter with small transportation cost.

Marsh stockholders have received word that arrangements have been made to use the Gertie tunnel for development at depth. "It seems to have been the unanimous opinion of the stockholders at the annual meeting that the company's ground east of the Hecla and carrying the extension of the Russell vein should be promptly and aggressively developed," says the report.

The Marsh company plans to concentrate development in following the easterly extension of the Russell vein. The present drift will be continued for sufficient distance to prove the course and dip of the vein, when it is planned to open it at the elevation of the No. 2 Marsh tunnel, 1000 ft. below.

According to T. B. Cosgrove, the American Commander company is finding stringers of high-grade ore running into the foot-wall in the new tunnel that are expected to develop into a high-grade streak on the foot-wall and make into the milling ore on the hanging wall. A feature of the present situation is that tunnel No. 1, which has been driven 1500 ft., is beneath this point and a cross-cut of 70 ft. should tap the ore-shoot at a depth of 450 ft. A compressor is being put in No. 1 tunnel to supply air to the American Commander, the Independent Lead, and the West Hunter.

The Reed Level Mining Co. has completed mill improvements and the installation of the slime-dumping plant, flotation unit, and ore-drying process. Fourteen cars of lead-silver concentrate were shipped to the Bunker-Hill & Sullivan smelter with net returns of \$1000 per car, which paid the cost of operation at the present prices of these metals. Three stopes are being worked. Recently a shoot of milling ore 16 ft. wide, showing more than 18 in. of high-grade galena on the foot-wall, was opened.

Mackay.—Homer V. Jerkins, manager for the Empire Copper Co., states that the company has adopted a schedule of shipments of one car per day. Lessees on this property will thus be enabled to ship much of the ore which has accumulated since the threatened shut-down. The mine is in excellent physical condition and several cars per day could be shipped were it not for the excessively high freight-rates which make shipment of the lower-grade ore unprofitable.

At the Doughboy mine drifting has been commenced on the 450-ft. level, the depth at which the last ore was struck. Past shipments from the mine have shown an average of 54 oz. silver and 50% lead. The mine was equipped for development work last fall and new machinery has been installed this spring. An average of six cars per month will be shipped as long as the weather permits, these shipments to be made from the accumulation of ore resulting from development work.

MICHIGAN

Houghton.—One steamer has just taken out 3,100,000 lb. of copper, the cargo being valued, at the present price of the metal, at about \$400,000. Of this amount, 1,000,000 lb. was Quincy copper, this representing the largest shipment Quincy has made in many months. The bulk of its sales for a considerable period have been to a wire-mill in this district, which has taken as high as a million pounds in a month. Calumet & Hecla had in this cargo, 1,200,000 lb., bound for Germany, it being part of the German business already reported. The remainder, 900,000 lb., was Copper Range metal going to consumers in the East. The

shipment of this large cargo bears out the prediction that the opening of the season of navigation would witness a considerable movement of copper down the lakes and if business continues at the present rate the surplus will have been reduced to almost normal proportions by fall. The bill introduced in the Michigan legislature at its recent session by W. F. Miller, of Houghton, to permit mining companies to engage in manufacturing was tabled, but its provisions were enacted into law by adding them to the general corporation law as an amendment. While this gives the copper-mining companies of Michigan the legal right to engage in the manufacture of their copper into finished articles in this State, it is doubtful whether any manufacturing plants ever will be established here. If any of the companies go into the manufacturing business it is the belief of local officials that the plants will be established in industrial centres, perhaps in the East, on account of competitive and marketing conditions.

Copper Range has started work on the re-timbering of No. 3 shaft, Champion mine. The shaft began to cave two years ago and has not been in use since. The work is being done now because it is possible to get expert timbermen. It will require at least four months, as the shaft is in bad shape. The shaft is 2339 ft. deep and bottoms at the 21st level. Copper Range is still experiencing a big labor turnover. The number of men leaving the mines for work on farms or elsewhere is even greater than usual at this time of the year. It is difficult to account for this apparent restless feeling. No difficulty, however, is being met in filling the places of those who leave. On the present basis of operations the three Copper Range mines are producing at the rate of about 2,600,000 lb. of refined copper per month, or 31,200,000 lb. per year. This compares with 33,025,959 in 1919 and with 23,756,267 in 1920.

Champion is now hoisting at the rate of about 560,000 tons of 'rock' monthly, of which 555,000 is stamped; Baltic is hoisting about 218,000, of which 163,100 is stamped; and Trimountain is hoisting 124,000, of which 75,000 is stamped. The total rock tonnage per month is 902,000, while rock stamped totals 793,500.

The copper now being disclosed in the 6th level drifts at the Seneca property seem to indicate that ore persists with depth. The 6th level is showing up as well as any of the openings in the preceding levels. Good ore continues to come from stoping operations on the 4th level, north.

MISSOURI

Joplin.—There was an advance in price of lead during the week ended May 7, which brought the market up to \$60 for the major portion of the tonnage sold. There were reports of sales at \$61.50, but these were not verified. The demand was heavy but the sales were restricted, due partly to the fact that production is low and the surplus is strongly held. Zinc ores also showed some strength at \$26 per ton, at which price approximately double the tonnage was sold that was marketed the previous week. Sales have been growing increasingly difficult, due to the small production.

MONTANA

Butte.—Cross-cutting north from the Butte-Plutus company's shaft on the 400-ft. level for the Norwich vein continues. The wall upon which a deposit of ore has been found nearer the surface is expected to be reached shortly. —With a partial resumption of work at the Washoe reduction works it is announced that the Tuolumne Mining Co. will resume shipping silver ore to the Anaconda plant for treatment. The Tuolumne stopped ore shipments when the smelter closed down.—J. L. Bruce, manager of the Davis-Daly mines, described the new ventilating system at the Colorado mine at a recent meeting of the Montana Society of Engineers. He said that 9000 cu. ft. of air per

minute, traveling at a velocity of 600 ft. per minute, enters the mine through a large octagonal down-cast shaft, especially driven to provide ventilation.

Fergus County.—Fifty men are now employed by the British syndicate that is working the sapphire mines. Montana is the first State in the Union in the production of precious stones.

NEVADA

Alpine.—The suit brought by the Nevada Lincoln company to recover the silver mine of that name has been settled out of court and as a result work is to be started by a new company, which will be financed by G. S. Johnson, of Fort Worth, Texas. The Nevada Wilson was organized after Frank Wilson had bought the property, then owned by the Nevada Lincoln, at a sheriff's sale. Tasker L. Oddie, United States Senator from Nevada, at one time had an option to purchase the mine for \$135,000. The claims are developed to a limited extent by a 400-ft. tunnel cutting the vein at a depth of 150 feet.

Ely.—Prospecting of promising silverbearing lodes on McCoy creek is planned by J. O. McKernan, D. B. Bailey, and D. C. McDonald. In all, 27 claims have been located in recent years.

Fifteen feet of good ore has been exposed on a sub-level 27 ft. below the main tunnel of the Boston & Ely Consolidated mine. Stocks of first- and second-class ore are rapidly accumulating on the dump. S. H. Williams is resident manager.

Hornsilver.—Nothing has been heard yet of a decision being reached by the Tonopah Mining Co. following the examination of the Orleans mine by its engineers. It is said that the examination was the most thorough ever made by the Tonopah Mining with one exception and that the result was highly satisfactory.

Klondyke.—Seven lessees are working in ore on the Original Klondyke. Although no shipments are being made, the activity in the district is greater than ever before and ore is accumulating rapidly.

Lovelock.—The old Darby mill, at Vernon, has been started up, milling ore for the Seven Troughs Mining Co. on a former contract that was never finished. Brook Hartley is superintendent.

Pioche.—The new town of Silverhorn is now supplied with water through the recently completed pipe-line from the Nevada Silverhorn company's spring. A store has been opened and a stage-line has been established between Silverhorn and Pioche. J. Nelson Nevius has completed an investigation of the geology of the company's property.

Pioneer.—Fair assays have been obtained in the Pioneer Consolidated shaft for the first time since sinking was resumed. It is estimated that the objective, 800 ft., will be reached in about 60 days, according to W. J. Tobin, general manager. Track is being laid from the Starlight tunnel to the mill, and production of good ore will be made from this tunnel. The Mayflower is now letting leases. The Pioneer shaft is 660 ft. deep.

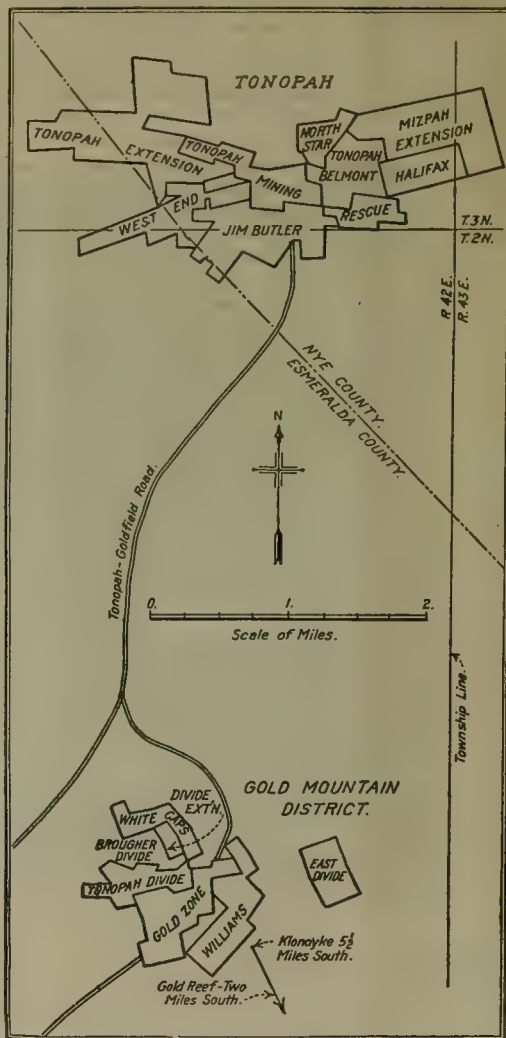

Rochester.—On May 10 the miners and millmen employed by the Rochester Silver Corporation voted unanimously to return to work after a two-weeks strike following a reduction in wages of 50c. per day.—The mill of the Nevada Packard company is again in operation. The mill was shut-down last August, the reason assigned being a shortage of water for the generation of electric power. Recent development in the mine is said to be favorable.

Silverton.—It is reported that the Tognoni group is to be taken over by the Silver Hills. There is a good showing of silver ore on the surface of this group, an assay of \$250 being reported from a 3-ft. width at one point.

Tonopah.—The West End Consolidated Co. shipped 31 bars of bullion, valued at \$68,350, as the product of the final clean-up for April; most of the ore comes from the big stopes in the Ohio Tonopah ground.

UTAH

Alta.—Operations have been resumed at the Louise Mining Co.'s mine, according to R. O. Dobbs, manager. Most of the work at present is being done in a drift from the

Tonopah and Divide

raise from the Maggie tunnel. One lot of ore, averaging \$66 per ton, was shipped from this raise last year.

American Fork.—Development work has been resumed at the Globe Consolidated property, according to John Cleg-horn, manager. The face of the adit is now 500 ft. from the portal, and it is planned to drive this about 250 ft. farther.—About a month ago, operations were resumed by the American Leasing Co., which has a long-term lease on the Belorophon, the Silver Wave, and Live Yankee groups of claims, adjoining the Globe holdings. This work is under the management of C. B. Ferlin.

Bingham.—The Utah-Apex Mining Co. will file in the Circuit Court of Utah its exceptions to the accounting for damages which the Utah Consolidated Mining Co. submitted

in accordance with the Court's decree. The Utah-Apex claimed damages to the extent of \$2,500,000. The Utah Consolidated filed a brief, acknowledging it should pay \$611,390 as principal and \$47,591 as interest, or a total of \$658,982, or about 25% of the amount claimed by the Utah-Apex. At present the Utah-Apex has a small force on development work and the upkeep of its plant. According to local gossip, the company will resume mining and milling operations when lead reaches 5½c. per pound.

At the present time, about 600 men are employed in and around the mines of this camp, and the payroll is about \$75,000 per month. Many of the miners thrown out of employment by the mining companies have taken leases, and in most cases, they are earning more than ordinary wages.

The Montana-Bingham Mining Co. will increase shipments of low-grade copper ore to approximately 100 tons per day, according to an official statement. The company has been making a profit on shipments of high-grade copper ore, which average about eight carloads per month. These shipments averaged from 9 to 18.65% copper, with some silver and gold. Development operations are progressing favorably. A raise from the main adit is expected to reach the upper workings very shortly. A winze sunk from the adit is now at a depth of 240 ft., in ore all the way. An additional force of 20 men will be put to work on the mining of the low-grade copper ore.

Eureka.—The Chief Consolidated Mining Co. shipped 21,144 tons of ore during the first quarter of 1921, averaging 0.49 oz. gold, 35.68 oz. silver, and 17.24% lead. The average gross value per ton was \$40.62; smelting, freight, and sampling totaled \$17.86 per ton, leaving a net value of \$22.76 per ton. The total profit for the quarter was \$43,064. A dividend of 5c. per share, or \$44,201, was paid. Development work during the period amounted to 1000 ft. Cecil Fitch, manager for the company, states that ore-reserves were fully maintained.

Ore-shipments for the week ending May 7 totaled 134 cars, as against 126 for the preceding period. The Tintic Standard shipped 50; Chief Consolidated, 32; Iron King, 16; Iron Blossom, 8; Dragon, 7; Eagle & Blue Bell, 6; Victoria, 4; Gemini, 3; Colorado, 3; Swansea, 2; Eureka Hill, Eureka Mines, and Mammoth, 1 each.

Drifting has been started on the 500-ft. level of the Lehi-Tintic property at North Tintic, according to Charles Zabriskie, manager. The drift is from a 500-ft. winze, which was sunk at a point several hundred feet from the portal of the adit.

The Eureka-Lily Mining Co. will resume operations on June 1. The holdings of this company adjoin those of the Tintic Standard. In order to begin work, an assessment of one cent per share has been levied. As only one shift will be employed, the proceeds of this assessment will be sufficient for five or six months work. Operations will be resumed on the 1400-ft. level, with the object of getting under high-grade orebodies found on the upper levels.

Kelton.—The Silver Hills Mining Co., whose property is 25 miles north of here, plans to resume work. W. J. Burridge, president, states that a shaft has been sunk to a depth of 180 ft. At 80 ft., the sulphide zone was entered and a 16-ft. deposit of ore was opened, averaging \$1 in gold, 15 oz. in silver, and 3% lead.

Moab.—The Utah Placer Mining Co. owns two groups of claims totaling 700 acres. Gravel from the Fishford group averages 60c. in gold and 90c. in platinum, while the second group averages \$1 in gold and 50c. in platinum per yard. The ground will be mined during the coming summer.

Park City.—Shipments for the week ending May 7 totaled 1112 tons, of which the Judge companies shipped 690; Ontario Silver, 257; and the Silver King Coalition, 165, as compared with 1450 tons for the previous week. The Judge

companies have about 500 men on the payroll at the present time, which is probably the largest number employed by any metal-mining company in the State.

Washington County.—Development work has been stopped at the property of the Silver Reef Consolidated Mines Co. The company will centre its efforts on the completion of a mill, as sufficient ore has been developed to warrant it.

ARGENTINE

Buenos Aires.—It is said that as a result of the rich discoveries of oil in the Comodoro Rivadavia field, Argentina may become one of the world's great sources of fuel. Well No. 128, which came in on February 28 with an initial production of about 100 bbl. per hour, is continuing to flow at approximately the same amount. The Comodoro Rivadavia oil-producing area is situated in the Territory of Chubut, in the region called Patagonia, and is more than 600 miles south-west of Buenos Aires. It was discovered in 1907 when a deep test was being made in an effort to find a water-supply. The Government, exercising its ownership of mineral rights, set aside 12,500 acres of land in the district and began the work of exploring the field. Later another 12,500-acre tract was reserved. Since that time 128 wells have been sunk and production has gradually increased up to the present. In 1920 the total production was more than 1,000,000 bbl. The oil is heavy with small kerosene and gasoline content and is used principally as fuel-oil, being sold to a number of industries in the country. Drilling depths are between 1500 and 1800 ft. Until well No. 128 was brought in, all the wells had shown small production, although several of them were gushers and had an initial production that passed the 100-bbl. mark. Practically every well drilled found oil in paying quantities.

BRITISH COLUMBIA

Sandon.—The Silversmith Mines has purchased the Ivanhoe mill, equipment, and mill-site from the Minnesota Mining Co. and purposes to spend \$40,000 in remodeling and enlarging this mill, according to John B. White, president of the Silversmith company. This will give facilities for treating a larger tonnage of ore. The present mill has a capacity of 75 tons daily. The equipment in this mill will be moved to the Ivanhoe mill. Work on the 41,000-ft. tram to connect the mine and new mill is to start shortly.

Stewart.—The Red Cliff group of claims situated on Bear river is reported to have been taken over by R. W. Wood and A. B. Trites, who purpose doing development work this year. The outcrop on the Montrose claim contains gold and copper.—P. H. Graham, who has charge of the installation of an eleven-mile aerial tramway for the Premier Mining Co., which will transport ore and concentrate from that company's property to tidewater, has taken over personal direction of the work. The tramway, the route of which parallels the wagon-road and is approximately 11½ miles long, is the second longest of its kind on the American continent. There are to be 150 ordinary towers and twelve tension towers, as well as three angle-stations and two terminals. Mr. Graham also is to supervise the construction of ore-bunkers at the wharf; they will have a capacity of 4000 tons.

Trail.—Ore receipts in gross tons at the smelter of the Canadian Consolidated Mining & Smelting Co. from April 21 to 30 totaled 12,056 tons. Of this the company mines contributed 12,023 tons and the Sally, Beaverdell, 33 tons. This brings the total for the year up to 139,816 tons.

Vancouver.—A Vancouver branch of the Yukon Order of Pioneers has been formed. Membership is limited to those who entered the Northland prior to 1900. At the first banquet of the organization there were present many who had 'mushed' over the historic Chilcoot and White Pass trails to the goldfields. The company included three ex-

governors of the Territory, F. T. Congdon, Alex. Henderson, and Capt. George Black; two ex-mayors of Dawson City, Henry C. McAulay, the first to hold that office in the centre of the Yukon, and R. P. McLennan; and other former Northerners of distinction. One incident of the affair was the declaration by Edward C. Russell, of Seattle, grand president of the Y. O. O. P., that greater things than have been are to come out of the Yukon in the way of commercial development when "the solid silver ores of the Mayo and other sections are exploited".

MEXICO

Durango.—Herbert E. Hambleton, a well-known mining man of Durango, has taken up a group of claims known as Las Granadas, situated in the Guanacevi district. The

was shipping high-grade ore to the Velardena smelter, now closed down.

Monterrey.—Plans have been made by a syndicate of New York men, which purchased the Cadamena mines in the western part of the State of Chihuahua from Manuel Raynol, for the construction of an ore-reduction plant to handle the ores of the property.——Ralph L. Van der Nailen has been granted a concession by the Mexican government for the exploitation of large placer deposits in the States of Sinaloa and Sonora. It is stated that the concession embraces 8000 acres in the beds of four rivers and their tributaries. The rivers are the Yaqui, Fuerte, Mayo, and Sinaloa.

Torreón.—E. Kreklau, who has figured prominently in mining in the Velardena district for some years, has re-

Bedding Ore at the Cananea Smelter, in Sonora, Mexico

property lies contiguous to the Aguaje, Peru, and El Oro mines, producers of gold and silver ore.——The Consuela No. 6 is a new filing on six mining claims made by Alfred Espana in the same district. A prospect shaft is being sunk on a well-defined vein of gold-silver ore.

In the Topia district of the State of Durango Romulo Gamboa has added another group of claims to his holdings. The property is to be named La Trinidad; it is situated near the La Paloma property.

Agustin Castro, Governor of Durango, is in Mexico City conferring with Federal officials in an effort to relieve the hardships throughout the State caused by the general suspension of the principal mines and smelters which have been closed down. Governor Castro asserts that if sufficient cars can be furnished to bring in fuel and transport the ores from the mines to the smelters some will resume operations giving employment to a great many men.

Work at Los Libres mines in the Velardena mining district was suspended this week, and W. H. Williams, manager, has left for the United States. This property belongs to the American-Mexico Mining & Development Co. and

cently returned from a business trip to Eagle Pass, where he completed arrangements with Leon D. Brooks and associates to take a one-half interest in seven groups of mines. The properties included in the transaction are the U. S., U. S. Extension, Wa-Hu, America, Dolores, Mexico, and San Lorenzo. A company with a capital stock of \$100,000 is to be formed, with headquarters in Eagle Pass, to be known as the U. S.-Wa-Hu Mining Co. In the meantime capital has been advanced to begin active development. The ore from the U. S. and U. S. Extension will be hauled to the station by automobile trucks.

It is insistently rumored that both coal and oil have been discovered in the State of Durango a short distance west of this city. Samples sent to the United States for analysis have proved of such worth that geologists will soon arrive to make an investigation of the region.

ONTARIO

Cobalt.—Some old properties which have not been operated for a number of years are being re-opened in the Cobalt district. The Victory Silver Mines, formerly the

Hylands, will explore the Keewatin-diabase contact at a depth of about 400 ft. Arrangements are being made to re-open the Silver Cliff mine. The Casey Mountain Syndicate will resume work at once on its property in Casey township.—Silver production from the Nipissing mine is averaging about \$5000 daily, while the total production in the district is at the rate of about \$12,000 daily. Cobalt oxide and cobalt metallics are being produced at a rate of about \$600,000 per year.—Good ore has been encountered on the Bailey Silver Mines in a raise from the 4th level.—The Silver Bullion property in the Gowganda district is to be re-opened this month.—Three machines are employed on the Keeley Silver Mines and at the 360-ft. level a vein is being opened up in which the silver content is from 25 to 30 oz. per ton across a width of about three feet.—The Kirkland Lake Proprietary (1919), Ltd., has removed its main office from Cobalt to Kirkland Lake, where energy is to be directed toward re-opening the Tough-Oakes and the Burnside mines, both of which are controlled by this concern.—The Mining Corporation of Canada has put a small force of men to work on its Buffalo property. Remodeling of the reduction plant to increase the capacity from 200 to 300 tons is now nearly completed.

The Keeley Silver Mines has been re-opened and a force of 30 men is engaged in developing the main body at the 360-ft. level. No effort will be made this spring to operate the new 20-stamp mill unless the price of silver increases.

High-grade ore is being developed on the Castle property at Gowganda, and arrangements will be made this year to erect a mill to treat the medium-grade ore which occurs in close proximity to the high-grade ore-shoots.

Kirkland Lake.—The Wright-Hargraves mill went into operation on April 26 and has since been working smoothly, treating between 100 and 125 tons of ore daily. Its estimated capacity is 175 tons, but this amount will not be handled until underground work has been further advanced.—The Lake Shore during March produced \$21,675 from the treatment of 1910 tons of ore. No. 1 vein has been cut south of the shaft at the 600-ft. level, where it shows a width of 12 ft. and is more heavily mineralized than on the 400-ft. level. A cross-cut on the 600-ft. level has entered the fracture in which vein No. 2 occurs. On the 400-ft. level a stope 350 ft. long and averaging 11 ft. wide has been opened, the ore in which averages \$28 per ton. Machinery to increase the capacity of the mill to 100 tons daily is on the way.

Larder Lake.—The new three-compartment shaft on the Kerr-Addison property of Canadian Associated Goldfields has reached a depth of 260 ft. Reports of high-grade finds on the property are confirmed. It is officially stated that the work of the past few months has been of importance in determining the character and continuity of the ore-shoots.

Ottawa.—A new amendment to the oil regulations provides that in view of difficulties in transportation the time fixed for the installation of machinery may be extended from one year from the date of the lease to a period not exceeding two years from that date.

Sault Ste. Marie.—Oil is reported to have been discovered on the Jennison farm six miles from the city.

YUKON

Mayo.—The Guggenheims are opening up new rich claims and are finding good ruby silver. The Northwest Corporation, a subsidiary company of the South American Gold Fields, has secured fifty claims. The opportunities for obtaining ground with small capital will be limited after next summer. Engineers for the Canadian Pacific Railway Co. are investigating property on the Christable creek slope of Keno hill, and others are prospecting the Rambler, Look-out, Stand To, Patterson, and Cameron mountains.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

William T. MacDonald is at Salt Lake City.

Clifford G. Dennis has returned to San Francisco.

Philip N. Moore has returned from Washington to St. Louis.

James A. Haney has returned from Kantishna, Alaska, to Seattle.

Ross B. Hoffmann has returned to Oakland, California, from London.

A. J. Beaudette sailed from New Orleans on May 12 on his way to Colombia.

C. C. Brayton is visiting mining districts in Arizona, Montana, and Utah.

W. H. McKinney Jr., of the Belgian Congo, West Africa, is at Newark, New Jersey.

W. E. Thorne is on his way from New York to South Africa by way of London.

Walter E. Gaby is at Pachuca, Mexico; he will return to Tezuatlan in three months.

H. Laycock, who has been with the Rosario Mines, in Honduras, is at Berkeley, California.

Edward R. Knowles has joined the engineering firm of Murrie & Company, at 74 Broadway, New York.

H. J. Gundlach is general manager for the Mine & Smelter Supply Co., in place of **W. L. Loveland**, who has resigned.

Brokaw, Dixon, Donnelly, Garner & McKee have removed their offices from 90 West street to 120 Broadway, New York.

John M. Fox has opened an office as examining and operating mining engineer in the Holbrook building, San Francisco.

James P. Gaskill, of Los Angeles, sailed from San Francisco on May 17 on his way to the Copper River district, Alaska.

S. C. Thompson has been appointed consulting engineer to the Kirkland Proprietary Mines Ltd., operating in Ontario.

O. F. Riser has resigned as mill-superintendent for the Chino Copper Co. at Hurley, New Mexico. He is now at Salt Lake City.

C. P. Bowie, petroleum engineer for the U. S. Bureau of Mines, has returned to San Francisco from the Santa Maria oilfield, California.

James Irving, of Los Angeles, has made an examination and report on the properties of the Silver Dome Mining Co., in Yuma county, Arizona.

Stanley A. Easton, manager for the Bunker Hill & Sullivan M. & C. Co., has been appointed a member of the State Board of Education of Idaho by Governor D. W. Davis.

Frank T. Snell has resigned as general foreman for the Nevada Consolidated Copper Co. to become associated with the Trojan Powder Co., with offices in the H. W. Hellman building, Los Angeles.

A. G. McGregor, of Warren, Arizona, sailed from New York on May 11 for a six weeks trip to Peru, where he will inspect the new smelting work that he designed for the Cerro de Pasco Copper Corporation.

M. J. Gavin, oil-shale technologist of the U. S. Bureau of Mines at Salt Lake City, will give an address on May 24 at Chicago on 'Oil Shale and Its Value as a Fuel Resource' before the International Railway Fuel Association.

J. C. Dick has resigned as chief of the Natural Resources Subdivision of the Income Tax Unit at Washington, D. C., and has resumed his practice as consulting mining engineer, with offices in the Walker Bank building, at Salt Lake City.

Eastern Metal Market

New York, May 11.

A fairly strong tone pervades all the markets; in some prices are higher.

Foreign buying of copper has been active but domestic purchases are small. Prices are firmer.

The tin market is steady and quiet after a few days of activity.

Lead prices have advanced again and the market is strong.

The zinc market is exceedingly dull but prices are steady.

Antimony is unchanged.

IRON AND STEEL

After one of the quietest weeks of the year in the matter of new orders, the steel industry is more confirmed in the view that for some time it may look for a succession of hummocks and troughs, with no long continuance of either, says 'The Iron Age'. The more cheerful sentiment of the two preceding weeks did not improve orders booked to the degree expected.

British pig-iron output was only 60,300 tons in April and the month's total of steel ingots was but 68,400 tons—both showing the paralyzing effect of the coal strike. Current operation is at less than 10% of the rate for 1920.

COPPER

The buying for the Far East which has characterized the past two or three weeks has now been supplemented by purchases from several European countries. At the close of last week, buying by England, France, Germany, Italy, and China, as well as Japan, aggregated 4,000,000 to 5,000,000 lb. The foreign situation is much better and when the reparation matter is settled, it is expected that the Central Powers will be more active. Sales for foreign consumption are usually at a higher level than prevailing domestic prices. Activity in the part of domestic buyers is by no means brisk. Inquiry is better, however, and it is expected that if foreign buying continues it will have a beneficial effect on the domestic demand. Electrolytic copper is quoted at 12.75c., delivered, or 12.50c., New York, for early delivery, with as high as 13 to 13.25c. asked for shipment into July. The lower price of 12.62½c., delivered, has largely disappeared and the market is stronger. Lake copper is only moderately active at 13c., delivered, or 12.75c., New York.

TIN

Starting a week ago Saturday a fairly active buying movement in tin set in; this continued until the end of the day on May 4, or last Wednesday. Fairly liberal sales were made which were confined largely to two tin importers. While consumers were purchasers in volume, the greater portion was taken by one dealer. The positions as sold include May-June and July-August from the East, with 32c. bid at the close on May 4, but there were then no sellers. During the movement spot tin was largely neglected as well as closely held. About this time sharp advances were made in London, on Thursday, May 5, amounting to £6½ per ton, but this at once choked off purchasing on this side and was regarded as a wrong policy. Since then the market has been stagnant and it is believed that, had the rise in London been more gradual, there would have been much more buying by consumers here. Spot Straits tin has hovered around 33c., New York, most of the week with the quotations yesterday at 32.25c. The London market is higher than a week ago by about £5 per ton, the quotations yesterday having been £173 10s. for spot standard, £175 15s. for future standard, and £179 10s. for spot Straits. The Singapore

price Monday was £181 per ton c.i.f. London. Arrivals thus far this month have been 510 tons, with 1490 tons reported afloat.

LEAD

Two more advances have been made by the American Smelting & Refining Co. in the last week. On May 4 this producer raised its price to 4.75c., New York and St. Louis, and again yesterday a further advance was announced to 5c., both districts. The outside market had already reached this level. Buying has been good, but production and stocks are not heavy, which accounts in part for the market's strength. It is understood that the leading interest is not a seller at present, disposing of its May shipment metal at its average price for May. Outsiders are selling at 5c., New York, and taking most of the business.

ZINC

There has been no revival from the dullness into which the market fell about a week ago. Demand has fallen off, if anything, but prices are fairly steady at 4.95c., St. Louis, or 5.45c., New York, for prime Western for early delivery. A small lot is said to have sold at slightly under this, but a large majority of the producers adhere firmly to the above quotations. Large sellers are not eager to part with their output. The ore position is such that, because of higher prices, stocks have not been greatly exhausted by the advance recently in the metal.

ANTIMONY

There has been no change in conditions or prices. Wholesale lots for early delivery are quoted at 5.25c., New York, duty paid.

ALUMINUM

The market is unchanged and inactive at 28c. per pound f.o.b. plant, for virgin metal, 98 to 99% pure, from the leading producers in wholesale lots for early delivery, while the same grade can be bought from other sellers at 23 to 23.50c., New York.

ORES

Tungsten: No changes are noted but the market is fairly firm. Sellers generally are not inclined to sell pending tariff bill settlements. Quotations are largely nominal at \$3.25 per unit for Chinese ore with high-grade Bolivian ore at about \$4 per unit.

Ferro-tungsten is unchanged at 58c. per pound of contained metal in lump alloy, guaranteed as to purity.

Molybdenum: Quotations are nominally unchanged in a dull market at 55 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: Offerings below prevailing quotations are heard of, but there is no business reported. Prices are nominal at 25 to 30c. per unit, seaboard.

Manganese-Iron Alloys: There is almost no demand for ferro-manganese, but the market for spiegeleisen is more active. Two or more carloads have been sold and there are inquiries before the market involving about 500 tons. The 20% grade is selling at \$32, furnace. Quotations for ferro-manganese are unchanged at \$90, delivered, for the American and \$100, seaboard, for the British. The ferro-manganese production in April, according to 'The Iron Age', was 9466 gross tons, which is about half the monthly average for the first quarter. The spiegeleisen production last month was 14,744 tons, or much above the monthly average last year.

EASTERN METAL MARKET

(By wire from New York)

May 16.—Copper is quiet and firm. Lead is dull but steady. Zinc is inactive but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

OUR TRADE WITH GERMANY EXCEEDS THAT PRECEDING THE WAR

Whatever may be the general effect of the reparations agreement upon the general trade of Germany it is quite apparent, says a statement by The National City Bank of New York, that our sales to that country in the fiscal year 1921 will be bigger than in any year in the history of the trade between the two countries.

Prior to the War we were selling to Germany about \$300,000,000 worth of merchandise per annum, making the highest record in 1913, \$352,000,000, having ranged from \$258,000,000 in 1910 up to \$352,000,000 in 1913, while the figures thus far received on our trade for the fiscal year 1921 indicate that the total of exports to Germany will reach or perhaps exceed \$400,000,000. In the nine months ending with March 1921 they were \$312,000,000, or more than to any European countries except Great Britain and France, and were running in recent months at over a million dollars per day, suggesting that the total for the twelve months ending with June 30 will probably exceed \$400,000,000 as against the high war mark of \$352,000,000 in 1913.

On the import side the total from Germany in the fiscal year 1921 will probably amount to about \$100,000,000 against \$185,000,000 in the year immediately preceding the War. While nothing can yet be determined as to the effect of the proposed tax of 26% on the value of Germany's exports, there is reason to believe that the merchandise which she is sending to us will total for the fiscal year 1921 about \$100,000,000 in value, the total for the latest available month, March, having been \$7,368,000 as against only \$4,952,000 in February 1921, thus indicating a rapid growth in our imports from Germany.

The principal articles forming this newly developing trade with Germany are, on the export side, foodstuffs, raw cotton, copper, and other manufacturing material, and on the import side, coal-tar dyes, potash chiefly for use as fertilizers, furs, glassware, gloves, musical instruments, sugar-beet seeds, a small quantity of beet sugar, toys, wood pulp, and certain cotton manufactures. Of raw cotton the exports to Germany for the nine months for which figures are now available were greater than to any other country except the United Kingdom and amounted in value to \$87,000,000; copper, 91,000,000 lb., valued at \$14,000,000, and only exceeded by the shipments to France which were \$16,000,000; while of food her takings were of flour which amounted in the nine months ending with March to \$13,000,000, while of wheat and flour her takings in the nine months ending with March were approximately \$57,000,000.

Of special interest are the figures showing the principal articles which we are now importing from that country. Figures of the Department of Commerce show that our imports from Germany in the calendar year 1920 included \$3,825,000 worth of muriate of potash, \$7,084,000 of manure salts, \$3,383,000 of kainite, a fertilizer, \$5,436,000 of beet sugar, \$1,585,000 worth of coal-tar colors and dyes, \$3,088,000 worth of furs, and \$1,190,000 worth of toys of which dolls and parts thereof were \$1,051,000.

Company Reports

CAMP BIRD, LIMITED

Report for the year ended June 30, 1920.

Property: Mine and mill in Colorado.

Operating Officials: William J. Cox, general manager; T. H. Woods, superintendent; J. T. Boast, mine foreman.

Financial: Profit for the year, £64,717 14s.; dividends, £45,473 15s.; balance forward, £37,440 5s. 1d.

Development: 4609 feet.

U. S. SMELTING, REFINING & MINING COMPANY

Report for the year ended December 31, 1920.

Operating Officials: C. E. Allen, D. D. Muir Jr., W. A. Howard, O. J. Egleston, R. E. Hanley, D. R. Muir, E. L. Young, M. W. Beckwith, A. P. Anderson, G. H. Clevenger.

Financial: Earnings, \$6,777,000.07; profits, \$2,909,274.82; dividends, \$1,702,225 and \$1,755,575.

General: The silver and gold output of the Cia. de Real del Monte y Pachuca was the largest in its history. Developments at the new properties, including the Arevelo, are favorable.

SANTA GERTRUDIS COMPANY, LIMITED

Report for the year ended June 30, 1920.

Property: Mine and mill at Pachuca, Mexico.

Operating Officials: H. Rose, managing director; C. A. Lantz, general manager; F. H. Walsh, general superintendent; J. F. Berry, mine superintendent; W. E. Crawford, milling superintendent.

Financial: Profit for the year, £172,384 6s. 4d.; dividends and directors' remuneration, £151,723 16s. 10d.; balance carried forward, £28,982 11s. 11d.

General: The company's holding on the Compañía de Santa Gertrudis, S. A., and the Compañía Beneficiadora de Pachuca, S. A., remains unchanged.

NORTH BUTTE MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines at Butte, Montana.

Operating Officials: N. B. Braley, general manager; L. D. Frink, superintendent.

Financial: Income, \$3,101,404.36; expenditures, \$3,677,637.54; deficit, \$576,233.18.

Production: 312,982 tons, for 16,576,510 lb. copper, 693,633.02 oz. silver, and 1004 oz. gold; 2235 tons from the Birta mine produced 90,309 lb. copper.

Development: Granite Mountain mine, 19,100 ft.; Sarsfield mine, 3002 ft.; Birta mine, 269 feet.

General: Operating efficiency has been maintained in a satisfactory manner; a larger footage of development was done in a smaller number of shifts.

INSPIRATION CONSOLIDATED COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill at Miami, Arizona.

Operating Official: T. H. O'Brien, general manager.

Financial: From sales of copper, \$10,033,706.61; net income for year, \$2,294,276.08; dividends paid, \$4,136,884.50.

Development: 17.17 miles; no additional ore was developed.

Production: Milled, 5,078,338 tons assaying 1.139% copper; tailing assayed 0.320% copper; total production of copper, 79,453,740 lb. at a cost of 14.173c. per pound.

General: During the year two additional Oliver filters were erected. Experiments in leaching and flotation of mixed ores were discontinued. The results of these tests gave satisfactory assurance that the ores are amenable to

such treatment. There was no change in the wage scale of the Globe-Miami district during the year; wages of all employees of the company were reduced \$1 per shift on January 1, 1921. Freight on copper to the refineries remains at more than 100% higher than pre-War cost.

YUKON GOLD COMPANY

Report for the year ended December 31, 1920.

Property: California and Idaho; Jarbidge, Nevada; Yukon Territory; Federated Malay States.

Operating Officials: O. B. Perry, general manager; C. H. Munro and J. B. Newsom, examining engineers in Malaya.

Financial: Total production, \$1,325,036.69; net operating income, \$304,387.05; net deficit for the year, \$393,223.47.

Production: Dawson dredging, 1,226,578 cu. yd. for \$415,030; California dredging, 4,900,726 cu. yd. for \$494,490; Idaho dredging, 1,295,900 cu. yd. for \$96,332; Dawson hydraulics, 1,702,264 cu. yd. for \$284,969; Nevada lode mines, 41,248 tons for \$354,360; Mayo silver lead mines, 875 tons for 199 oz. silver and 60% lead.

General: The total developed acreage of tin fields in the Malay States is reported to contain 95,000,000 lb. of recoverable tin.

TONOPAH BELMONT DEVELOPMENT COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at Tonopah, Nevada.

Operating Officials: F. Bradshaw, general manager; A. Silver, superintendent of milling; L. R. Robins, superintendent, Tonopah; W. H. Royston, mill superintendent, Tonopah; O. McCraney, superintendent, Shawmut.

Financial: Net earnings from the operation of the mine and mill, \$457,826.49; total credits, \$662,358.23; net profit for the year, \$603,146.72; dividends, \$150,000; paid January 1, 1921, \$75,000, April 1, 1921, \$75,000.

Production: The Tonopah mill treated 158,634 tons of ore for a recovery of 94.65% of the gold and 92.22% of the silver.

Ore-Reserves: 124,757 tons, positive, at the Belmont mine.

General: All the silver produced from the Belmont mine has, since the Pittman Act went into effect, been sold to the Government. The ore-reserves value is based on silver at \$1 per ounce; it would be materially reduced should this price not be maintained by the Government.

MIAMI COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at Miami, Arizona.

Operating Officials: F. W. MacLennan, general manager; J. H. Hensley Jr., mine superintendent; F. W. Solomon, mill superintendent; R. B. Yerxa, assistant mill superintendent.

Financial: Net earnings, \$2,888,479; dividends, \$1,494,228.

Production: Ore milled, 1,801,958 tons; copper produced, 55,581,328 lb. for a total cost of \$0.08177 per pound.

Development: 41,925 ft.; ore-reserves, 10,723,410 tons at 2.26%; 36,000,000 at 1.06%; and 6,000,000 tons at 2%.

General: J. Parke Channing, in his report, states that the caving method of mining became a matter of routine during the year, with a reduction of mining cost of 24 cents as compared with 1919. Milling cost was reduced 10 cents, and other reductions brought the total cost at the mine to 39 cents below that of 1919, or about 1 cent per pound of copper produced. Development in the lower part of the main orebody during the year was extensive and resulted in adding about 1,500,000 tons to the previous estimate, with a slight lowering of the grade.

Book Reviews

Gas Torch and Thermit Welding. By Ethan Viall. Pp. 425, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, \$4.

Electric Welding. By Ethan Viall. Pp. 399, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, \$4.

Besides being by the same author, these books concern the two principal divisions of what is coming to be called autogenous welding, this term including all welding other than forge-welding. They are therefore companion volumes and may well be discussed together. Mr. Viall has been on the staff of the 'American Machinist' for several years, and has been editor for the past year and a half. He has written several books in the past few years, and has engaged in many other useful activities. Furthermore, while a man of great ability, he is not a superman, and probably requires some time each night for sleep. The arts with which these books are concerned are relatively new; progress has been rapid.

Under the conditions outlined above, we would naturally expect to find errors, some small, some important, that had been overlooked in the haste of compilation, and our expectations would be verified. For instance, on page 74 of 'Gas Torch and Thermit Welding', appears the statement, "Cast-iron cannot be satisfactorily cut with a gas-torch." On pages 267-273 of the same volume appears the full report of the success of Stuart Plumley and F. J. Napolitan, of the Davis-Bournonville Co., in cutting cast-iron.

Under these conditions also, we would expect to find reports of the experience of individual investigators and operators, as given in magazine articles, also descriptions of apparatus and records of performance as furnished by the commercial companies, and here also we would not be disappointed. If, however, we continued our study, and sought thorough and impartial presentation of both sides of disputed questions regarding apparatus or practice, we would find it lacking. For instance, there is nothing in the book on electric welding to help a man who is uncertain whether to buy a direct- or an alternating-current welder. It is true that support of the claims of either side of this disputed question would be out of place, but it is in helping the individual in solving his own particular problem in such questions that one of the most important services of a technical treatise lies. And it is just here that the books in question are again found wanting. Progress in the arts covered may be so rapid that the publication of a really standard treatise is still impossible, but it would be entirely possible to present the material available in such a manner as to inform the reader fully as to the progress that has been made to date. This has not been done.

However, both books will be useful to those engaged in, or interested in, welding. There is a large amount of valuable material that has not appeared before in book form. In fact, practically the entire contents of both books are valuable, and the illustrations are excellent. But the material is poorly edited and incomplete. A. T. P.

Gasoline and Other Motor Fuels. By Carleton Ellis and Joseph V. Meigs. Pp. 670, ill., index. D. Van Nostrand Co., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, \$10.

The production of motor fuels has become, almost overnight, one of the most important, if not the most important part of the business of petroleum refining, and processes have also been developed for obtaining motor fuels from other substances. In the present volume a general discussion of refinery methods lays the foundation for a detailed description of cracking processes, which occupies nearly half

the book, and includes those processes that have been described only in patent applications as well as those that have been demonstrated in practice to have a commercial value. The production of motor fuels from gases, from oil-shale, and from asphalts and cannel coal is also discussed, as well as the production and use of alcohol and benzol in engines. There are two appendixes, one containing general statistics of the petroleum industry, and one discussing the by-product coke industry. The treatise will be a valuable reference book for anyone engaged in the distillation of motor fuels or in the design of internal-combustion engines.

Thermodynamics and Chemistry. By Frank H. MacDougall. John Wiley & Sons, New York. For sale by 'Mining and Scientific Press'. Price, \$5.50.

This book has been written to meet the needs of advanced students of chemistry. Although a course of thermodynamics is indispensable to students of physical chemistry, it is no less desirable for the organic chemist, who finds that he must make use of physico-chemical methods and laws, the full significance of which will hardly be clear to one who is not familiar with their thermodynamic foundations. The contents of the book are as follows: Temperature; actual gases; heat; first law of thermodynamics; application of the first law; thermo-chemistry; second law of thermodynamics; deductions from the first and second laws; thermodynamic functions and equilibrium; fusion, evaporation, and sublimation; the phase rule; application of the phase rule; chemical equilibrium; electromotive force; surface tension and adsorption; radiation; the quantum theory; the Nernst heat theorem.

The Recovery of Nitrate from Chilean Caliche. By A. W. Allen. London, Chas. Griffin & Co., Ltd., Exeter street, Strand, W.C.2. Price, 6s.

The purpose of this booklet is to point a way to a more economical and efficient process, which preserves the simplicity of the Shanks system and, at the same time, permits of the complete treatment, to a satisfactory and logical conclusion, of material that is now considered valueless. The monograph includes a description and a criticism of the extraction and crystallization stages of the Shanks process, together with an analysis of the results of the present method of treatment. Features of desirability in an alternative scheme are discussed, as a preliminary to a description of the new process. Other subjects dealt with include the heating of nitrate solutions, the production of commercial nitrate from liquors extracted, the evaporation of water from nitrate solutions, and the use of the grainer for evaporation and crystallization purposes. A vocabulary of terms used in Chilean nitrate technology is appended.

Technical Methods of Analysis. Edited by R. C. Griffin. New York: McGraw-Hill Book Co., Inc. Pp. 666, 5½ by 8, ill. For sale by 'Mining and Scientific Press'. Price, \$6.

This treatise contains a representative selection of analytical methods that have been adopted as standard in the laboratories of Arthur D. Little, Inc. The methods described have been used and proved as satisfactory, or are standard procedures that have been accepted as reliable elsewhere. The book is remarkably complete, the subjects dealt with including the preparation of reagents, general inorganic and organic analysis, the analysis of metals, paints, oils, fats, waxes, soaps, fuel, wood, paper, textiles, and foodstuffs. Methods for the analysis of a number of miscellaneous substances are added, and the book concludes with a series of tables, with analytical factors and volumetric solutions; it has been written to conform to a standard style throughout, it has been carefully edited, and it is a creditable addition to the McGraw-Hill International Chemical Series. It should be recognized as an essential in every well-appointed laboratory.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

SULLIVAN DRILL-SHARPENERS

The drill-sharpener illustrated herewith is a compressed-air machine for making rock-drill and hammer-drill bits by hammering.

Much deserved emphasis has been laid, in the past four or five years, on the importance of proper drill-bits. This cannot be too strongly urged. No matter how carefully the drills have been selected for the work to be done, or how efficient they may be, poor drill-steel, steel improperly forged or tempered, or bits of unsuitable shape, or not uniform in gauge, will nullify the excellence of the drilling machines. It may be truly said that the entire mining organ-

3. Uniformity: Bits are perfect in shape, with all wings of the specified length, thickness, and angle of cutting edge. Bits are made to the exact gauges called for, and the steels in a set 'follow' in the hole, ensuring steady progress and reducing the danger of stuck bits, with the resulting delay and wear and tear on the drill.

These advantages and their stimulating effect on drilling progress are so important that the mechanical drill-sharpener has come to be regarded as a part of a drilling outfit almost as essential as the steel itself. The variety of forge-shop work, aside from making bits and shanks, accomplished on a sharpening machine, also adds to its practical value. The Sullivan sharpener consists essentially of a clamp or vise, an upsetting hammer, and a swaging hammer, mounted on one compact frame.

The especial advantages and features of Sullivan sharpeners may be summarized as follows:

1. Steel Quality: Gradual hammer-action preserves the quality of the steel and adds strength and toughness, while a

2. Low Forging-Heat is sufficient for proper working. The highest carbon steel is handled by this method without danger of burning.

3. Accuracy: The dies used for upsetting and gauging the steel ensure accurate and exactly uniform work. All bits are correctly gauged and are perfect in shape.

4. High Capacity: New bits may be made from bar-stock in one minute or less. Ordinary dull bits may be re-sharpened at the rate of 100 to 140 per hour.

5. The Variety of Work that may be performed on these machines.

6. Air-Power Economy: Air is used only while the sharpener is actually at work.

7. Compactness: The quick-acting air-vise eliminates long frames and tail blocks for holding the steel.

8. Convenience and ease of operation.

9. Reliability, ensuring continuous operation, due to abundant strength and excellence of materials and construction.

10. Increased over-all drilling efficiency results from the improved quality of the steel, the reduction in bit breakage, and the reduction of wear and tear on the drills with its consequent delays.

Bits forged by the Sullivan 'all-hammer' process cut faster and farther and lose their edge and gauge less rapidly than bits made and sharpened by other methods. Old drillmen know, and tests have demonstrated repeatedly, that a bit will cut more feet of hole after it has been re-sharpened a few times under the blacksmith's hammer, than when made up for the first time. This is simply an example of the well-known fact that hammering not merely does not injure the quality of steel, when properly heated, but that it actually refines the metal, imparts to it a closer, more

Swaging a Bit With a Sullivan Drill-Sharpener

ization is pyramided on the drill-bit. Poor bits mean lost holes, undue drill wear and breakage, delay in repairing them, loss of time and curtailment of output. There is no better insurance for satisfactory progress or production than an adequate supply of good drill steel, properly sharpened, shanked, and tempered. A small investment for modern blacksmith-shop equipment, a little thought spent in arranging it systematically, and a policy of encouragement toward the smith and his helpers will pay large returns in improved drilling efficiency.

Advantages of machine-forging of drill-bits include:

1. Rapidity: The drills and their operators are not left idle for lack of sharp steel.

2. Labor Economy: A smith and a helper can handle as much steel on a modern sharpener as several crews sharpening by hand.

regular, structure, and renders it better capable of resisting shock and strain.

The bit is not upset to final shape and gauge at one operation, nor are the wings drawn out to final thickness and form all at once. The bit is upset a little in the horizontal hammer, then drawn out a little under the vertical hammer. These processes are alternated until a perfect bit is formed, in accordance with the best accepted methods of hammer-working steel. Further, distributing the work in this manner eliminates the possibility of raising fins on the edges and corners of the bit. If the upsetting is completed at one time, or the wings drawn out all at once, weakening strains are imposed on the steel, and its structure is distorted. The convenient arrangement of the working parts in the Sullivan sharpener permits this alternation to be rapidly accomplished and the bit properly worked, under the eye of the operator.

The heats required for proper handling of the steel in the Sullivan sharpener are moderate, ranging from 1500° to 1750°F., and high-carbon steel runs no danger of having its carbon content burned out during the process of sharpening. Not only this, but the steel may be worked longer, that is, at a lower heat, than is possible if methods other than hammering are employed; and the steel is not injured by such work. One heat is sufficient for nearly all processes performed by Sullivan sharpeners.

Proper heating of the steel is very important. When the customer has gone to the trouble and expense of determining the kind of steel that will give him the best service, and has secured this steel from the manufacturer, the mistake should not be made of employing sharpening methods that involve detriment to the steel by irregular or dangerous temperatures. When a bit has once been burned, its life and cutting power cannot be restored. A crumbling edge and rapid wearing or chipping of the corners are evidences of this damage; and this means decreased drilling speed, loss of drill-runners' time, and increased handling, labor for the blacksmith, and steel cost, due to the necessity of cutting off the burned bit entirely and making a new one.

The way to avoid such losses in material and efficiency is, first, to employ a sharpening machine, such as the Sullivan, which does not require dangerous heats for its successful operation; and, second, to provide a forge or furnace for heating the steel, which may be regulated so that overheating is impossible.

There are on the market oil- and gas-furnaces, with proper regulating devices, that provide a quick uniform heat and are convenient and economical of fuel. Such an outfit is a great improvement over a coal forge, in which it is almost impossible to keep the heat uniform while even one lot of steel is being heated, and in which the judgment and attention of the smith is the only protection against overheating.

In any case in which the amount of steel to be sharpened is sufficient to require the installation of a sharpener, it would seem exceedingly wise to purchase such a furnace. The expense is comparatively small, and the results gained in steel saving and increased drilling efficiency will pay for the investment many times over. The Sullivan drill-steel furnace has been designed especially for this service, and is securing remarkable results along the lines suggested above.

COMMERCIAL PARAGRAPHS

The Chicago branch store of the **Lunkenheimer Company** has been moved from 188 North Dearborn street, to 568 West Washington boulevard.

The **Stearns-Roger Manufacturing Co.**, of Denver, has been awarded by the **Catlin Oil-Shale Products Co.** a contract for new equipment for its plant at Elko, Nevada, including two large gas-producers, 12½ ft. in diameter. It is

understood that the design of this apparatus has been completed and that the work of construction will be started immediately in the shops of the **Stearns-Roger company** at Pueblo.

Rickard & Company, Incorporated, is the new corporate name for **Rickard & Sloan**, specialists in industrial and technical advertising. The office will continue to be at 25 Spruce St., New York.

Leslie H. Allen, who has recently been with **Fred T. Ley & Co.**, has joined the staff of the **Portland Cement Association**, 111 West Washington street, Chicago, as assistant manager of the **Cement Products Bureau**.

The **George H. Gibson Co.**, consulting engineers specializing in commercial research and advertising of technical products, has moved its offices in New York from the **Tribune building** to the **Hide and Leather building** at 100 Gold street.

The **Hardinge Company**, whose New York office is at 120 Broadway, announces the publication of the sixth of its series of 'Grinding Data Bulletins'. This Bulletin presents interesting data on the operation of the large-sized **Hardinge mills** in the mining field, not only where stage reduction is the custom, but also where the single-stage method is in use. The whole series of bulletins embodies information on **Hardinge mills** and other types of grinders, not only in the mining field, but in the industrial field as well.

The **Air Reduction Sales Co.**, manufacturer of 'Aircor' oxygen, acetylene, and welding and cutting-apparatus, has moved its executive offices from 120 Broadway and 160 Fifth avenue to 342 Madison avenue, New York. This move to uptown New York comes as a result of the company's outgrowing its former quarters. The concentration of all its general office departments in one building, it is thought, will make for more convenience and efficiency. Coincident with the announcement of this change is another to the effect that the New York district office will be situated at the **Aircor factory**, 191 Pacific Avenue, Jersey City. All correspondence and other communications heretofore directed to the district office should in the future be sent to the new address.

Homer J. Forsythe, manager of the construction division of the engineering department of the **du Pont Company**, has been transferred to the position of assistant general manager for the **Hyatt Roller Bearing Co.**, of Newark, New Jersey, a subsidiary of the **General Motors Corporation**. Mr. Forsythe was selected for this important position because of his wide experience in machine-shop work. During the War he was made manager of the combined **Wilmington shops**, which were one of the major divisions of the **duPont Engineering Co.**'s activities in the construction of material for the war plants. At the end of the War he was promoted to manager of the construction division of the engineering department, which position he held until his recent transfer.

Bulletin No. 223, issued by the **W. S. Rockwell Co.**, illustrates various types of burners for the use of oil- and gas-fuels for industrial heating. Emphasis is laid on the fact that the real question is not alone one of burner selection, but rather the successful conduct of a heating or heat-treating operation as measured by the cost of production of a quality product. The real 'efficiency' of a burner; the choice of type and size to suit the kind and pressure of the fuel and atomizing element; methods of attaching burner-plates; prices of different sizes in each type of burner; a chart showing the comparative cost per million B.t.u. at unit prices—these features will no doubt interest those readers who wish to keep in touch with developments relating to fuel and methods and means of utilizing it to the best advantage.

SALT LAKE CITY HOUSE

Save Freight Costs By Using Our Supply Depots

DO not forget that Massco Service brings the *best* of all lines of mill, mine and smelter supplies within easy reach of every operator.

Remember that the same organization which is responsible for the Wilfley Table and the Marcy Mill stands back of every item.

Massco salesmen will gladly explain the various lines and submit quotations.

Massco general catalogues are very useful and will be mailed on request.

SILVER coinage is again to come into its own in Russia, the Soviet government having authorized action in that direction; a complete change of policy, therefore, is in evidence. It was not so long ago that the bolsheviks explained that money of any kind was unnecessary in a country that was governed and controlled by the 'workers'. The change of front in Russia is apparently due to the peasants, who have become increasingly distrustful of the ruble notes, which have an absurdly low purchasing power.

DEEP regret will be felt by many of those engaged in mining that Franklin K. Lane's useful life should have ended so soon. The letter that he wrote just after he had undergone a severe surgical operation, and when the grim ferryman seemed yet to be beckoning him, is of poignant interest to his friends. He spoke of his early career and referred to the fact that he had escaped more than once from being shot while engaged as "a newspaper man". Whereupon he remarked with deep seriousness: "There must be public concern in what is printed as well as the truth, to justify it. That is something the newspapers should get to know in this country".

FAIRLY healthy conditions in the mining of precious metals in Mexico are indicated by the following statistics, those for 1920 having been issued recently by the Mexican Department of Mines:

	Gold		Silver	
	Kilogrammes	Ounces	Kilogrammes	Ounces
1917	23,542	756,891	1,306,988	42,020,579
1918	25,313	813,830	1,944,542	62,518,386
1919	23,586	758,306	2,049,893	65,905,655
1920	22,864	735,093	2,068,938	66,517,804

Since the end of last year the fall in the price of silver has checked the production of that metal, but a steady improvement in the mining of gold is still a favorable factor.

GERMANY'S terms of reparation, namely, those she appears reconciled to accept, are not easy to understand in detail. For example, it is supposed that the 25% export tax is a direct levy on the exporters; it is not; on the contrary, the stipulation reads that "the equivalent of the 25% levy shall be paid in German currency by the German government to the exporter". In short, the export tax is merely a measure of Germany's ability to pay; the proceeds of the tax are to be used in

paying interest on the bonds into which the reparations are to be funded. This is an important detail, especially if, as seems likely, any large portion of the bonds is sold to American investors.

SELF-DETERMINATION is one of the sticks of dynamite that ex-President Wilson threw into European politics, and, to speak concretely, D'Annunzio and Korfanty are two of the detonating caps that have caused particular explosions. Both are outlaws; moreover, they are pestilential nuisances in so far as they have made the European tangle the worse by their antics. Self-determination is a rank absurdity; it means a reversion to the jungle, for if all of us were to self-determine to what government we owed allegiance and to which authorities we cared to subordinate ourselves, the whole elaborate edifice of civilization, constructed in pain and travail during centuries, would disintegrate and tumble into a bolshevist abyss.

THE War Minerals Relief Commission has been reduced to a skeleton organization by the resignation of Messrs. Philip N. Moore and John F. Shafroth. They retired on May 20, leaving the third member, Mr. Horace G. Pomeroy, with the chief engineer to the Commission, Mr. J. H. Means, to dispose of the remaining appealed cases. Senator Shortridge of California has introduced a bill providing "for more liberal interpretation" of the War Minerals Relief Act. It remains to acknowledge the public service rendered by the two senior members of the Commission, particularly by the chairman, Mr. Moore. We have not agreed with his attitude toward some of those asking for relief and we think that his imputation of selfish motives to many of those who answered the national call to produce war minerals was mistaken, but we have never doubted that his own motives were honorable and sincere, and that he meant to do his duty in the unpleasant task allotted to him as head of the Commission.

EMPLOYERS of labor do not always realize that the wage factor depends, not so much on what a man receives, as on what he can buy with his earnings. Early in 1920 the employees of the Judge Mining & Smelting Company made informal complaint to the management in the matter of the high local cost of the necessities of life. As a result, the company, acting in conjunction

with its allied corporations, started a fully equipped store in Park City, at which merchandise was sold to all employees, and strictly on a cost basis. The annual report states that the men have been quick to take advantage of the innovation; the time and effort expended in putting the store on a working and self-supporting basis has been fully repaid by the benefits that have accrued. As a method of dealing with local profiteers, the idea might be adopted more widely.

SOME oil may still be squeezed out of Mexico's sandstone, in spite of the fact that many of the largest wells have 'gone to salt'. At least the predictions of the alarmists who profess to see the immediate exhaustion of the Mexican oilfields would seem to be a trifle premature in view of recent developments. Fifteen new wells, with an initial capacity of 650,000 barrels per day, have been 'brought in' during the last two months. The pessimist interprets this large new production as an indication of the rapid draining of the known fields; others contend that the peculiar geologic conditions of the Mexican oilfields make this inference unreasonable. One thing is inevitable: the fate of all oil-wells is to become saline, and those in the Tampico fields and in the other districts in Mexico will not prove to be exceptions. It seems obvious that what is required is to prospect and develop new territory. More intensive search would doubtless have been made already had not the insecurity of property frightened foreign capital. A definite and reasonable policy adopted by an established government would reassure those willing to finance exploration for, and exploitation of, new oilfields. The oil resources of Mexico are not even approaching exhaustion.

SILVER mined in Colorado and minted at Denver brings the producer less than the same silver minted at Philadelphia. This seems paradoxical; yet it is true, much to the chagrin of the politicians in Colorado who used their influence to have the Director of the U. S. Mint order the delivery at Denver of silver purchased under the Pittman Act. Their motive was the selfish one of assisting local industry; they never dreamed of the outcome of their activities. The reason is simple. The American Smelting & Refining Company smelts Coloradoan ores at Pueblo and at Leadville, but the semi-finished products, namely, pig-lead and matte, are refined at Perth Amboy, in New Jersey. It costs more to market at Denver the refined silver that comes from the Perth Amboy plant than to market it at Philadelphia, where it has been sold heretofore. The insurance, the expressage, and the interest charges increase, and the Guggenheims are most unlikely to hesitate to pass this additional cost back to the producer in the form of a deduction in his settlement for ores that he sells. This deduction has been fixed arbitrarily at three-fourths of a cent per ounce; the miners protest that it is too much, but objection gets them nowhere when there is no other purchaser for their ores. If it be possible for the politicians to profit by experience, they may take to heart the trite adage and next time 'look before they leap'.

The Institute Magazine

The discussion of the merits of the monthly magazine issued by the American Institute of Mining & Metallurgical Engineers, and the more recent suggestion by the San Francisco Section that it be discontinued, invites an appraisal of this particular publication and of others like it, as, for example, the magazine published by the American Society of Mechanical Engineers. These publications have grown out of the periodic bulletins issued by the secretaries of the engineering societies; at first they contained lists of new members, obituaries, and notices of future meetings, together with brief descriptions of past conventions; they were modest in size, taking the form of a thin pamphlet; they were sparing of expense, until the idea of using them as a means for obtaining income by aid of advertising led to an expansion in their scope and an enlargement of their volume into a monthly magazine. This contains the information previously distributed in the bulletins, plus a generous measure of piffle and padding, pictures and propaganda. Abstracts of technical papers are included, as well as an index, no better and no worse than the majority of such ineffectual attempts to issue a catalogue of current technical literature.

At the present time, owing to the character of its contents, the Institute magazine is not a serious business competitor of the technical press; that is to say, it does not attract sufficient advertising to hurt the legitimate press, and therefore we, for example, can view the subject with some measure of detachment and lay stress on the principle, rather than the property, involved. It must be clear, however, even to the casual observer, that if a man like Dr. Raymond were Secretary of the Institute, he could produce a publication that would cut into the advertising appropriations set aside by wide-awake manufacturers for the purchase of publicity in the technical press. In short, this exuberance of publishing activity on the part of the engineering societies may become a menace to the technical papers, and eventually threaten their very existence. Such a sequel conceivably might be regarded with equanimity by the engineering profession if the society publications could perform the service and fulfill the purpose of the technical press, or if the latter merited extinction. As to that, anybody taking the trouble to compare the current issues of the two mining papers, the one in New York and the one in San Francisco, with their back numbers, say, of twenty years ago, will find that in nothing relating to mining has there been more evident improvement than in the periodic literature devoted to the industry. On the other hand, if a comparison be made between the Transactions of the Institute today and the Transactions of twenty years ago, it will be found, we believe, that the gain is more of quantity than of quality. In 1901 the Transactions were edited with a loving care and an unflagging zeal that gave them a uniform excellence such as belongs to no other body of diverse technical writings. The quality could not have been so high if the quantity had not been kept within reasonable limits. We submit that

the editors and publishers of the two mining papers have performed their duty to the profession sufficiently well to be entitled to friendly consideration. Their business exists on a purely competitive basis and they ask only the favor of fair play. This they are not getting. The Institute magazine may be set down nominally at \$5 per annum, out of the \$15 paid as regular dues from members, but it would not have a thousand subscribers on its merits even at half that price; it goes to the members of the Institute because they have no choice in the matter; its publishers claim that it has 10,000 subscribers because it is mailed to that number of persons; and thereby they can make a misleading comparison with the subscription lists of the two mining papers. The comparison is misleading because the major proportion of the copies of the Institute magazine goes promptly to the waste-paper basket, but it is used as a plea for the purpose of obtaining advertising. In addition, the putative advertiser is asked to be impressed by the fact that the magazine is the official organ of the Institute and that any support given to it by the manufacturer will be appreciated by the influential gentlemen on the board of directors.

The only claim the legitimate technical press makes is that it is read, as well as received, by the persons to whom the advertiser desires to present his product; the directors of the technical press are not engaged in mining and they are not connected with smelting operations; they are publishers only. The editors and managers of the 'Mining and Scientific Press' are engineers, but they do not practise their former profession. *Ne sutor supra crepidam*. The whole procedure of Institute journalism may be compared to the starting of a local grocery by the Y. M. C. A., using its humanitarian affiliations as a means for creating a clientele; it is as if the U. S. Golf Association should establish a store for the sale of sporting goods. A closer analogy perhaps will be found in the activities of the National Geographic Society, one of whose circulars came into our hands this week. This circular apprized a neighbor that he had been "nominated for membership" by Mr. A. B. Blank, whom he did not know, and that his membership would make him "one of a group of persons of distinguished educational, industrial, and scientific service". All he had to do was to forward the annual fee of \$3.50, which would entitle him not only to the "fascinating articles in the Geographic Magazine" and to association with the truly great, but it would also give him "the right to nominate" his friends for membership in the Society! Was ever commercialism more ludicrously camouflaged? Again, we are reminded of a Mr. R. Stuart Browne, who about twelve years ago ran a paper in San Francisco called the 'Pacific Miner'. He needed subscribers, so he founded a society for the ostensible purpose of ministering to the greater glory of the profession, and devised the plan of giving membership in his society to every person subscribing for his paper. Besides this he authorized them to use a luminous tail of initials; if we remember correctly the suffix was M. A. I. M. & M., apparently in intelligent anticipation of the gentlemen in New York!

Joking apart, we submit that the Institute is spending energy and money on a publication that is not needed; its notices of meetings, lists of candidates, index, and other odds and ends could be distributed as formerly, in the shape of an inexpensive and non-competitive pamphlet. The interests of the profession are not all in the care of the Institute, excellent as may be the work it is doing; the technical press can claim fairly to have stood for those interests in the past and it shows no signs of apostacy in the present. The profession needs an independent journalism just as much as a central organization. Each has its function to perform, and each should be given a full opportunity to perform it. The technical press has progressed and is progressive; it is doing its share of good work; we submit that it is entitled to fair play. We appeal to the profession, and more particularly to the titular leader of our profession, Mr. Edwin Ludlow, the president of the Institute.

An All-round Engineer

At the last meeting of the American Mining Congress, at Denver, in November, a certificate of honorary life-membership was handed to Mr. David W. Brunton, and the incident evoked hearty applause. It served not only as an appreciation of his services as a director of that organization of mining men, but it marked the high esteem in which he is held in the mining fraternity. Shortly afterward we took an opportunity to interview him, as appears elsewhere in this issue. Mr. Brunton belongs to a group of Canadian-born Americans who have played a conspicuously useful part in our national mining industry. To that group belong Richard P. Rothwell and James Douglas among the honored dead; to it belong E. P. Mathewson and W. J. Hamilton among the honored living. Our young men, curious to ascertain the steps by which their seniors achieved success, will note that Mr. Brunton was fortunate, first, in coming of engineering stock and, second, in being educated at the University of Michigan. A touch of romance, that is, of the delightfully fortuitous, was given to Mr. Brunton's start in life by the visit of a gentleman from Colorado to the university at Ann Arbor. This stranger from the Rocky Mountains was the president of a mining company in search of a young engineer to take charge of a small property in the picturesque San Juan region. This first call to the mines proved abortive in its economic results, but it led to a new engagement, and to a critical event in Mr. Brunton's life, namely, an acquaintance with James Douglas. To know men is more than to know mines; the friendship that developed with Douglas was one of the good things of life. And many are the men who have been able to say that about James Douglas! It seems like the turning of old pages to read about the Hunt & Douglas process at Georgetown and then to find a mention of Joshua E. Clayton. Those early experiences in Colorado and Nevada did not seem to lead anywhere in particular but they gave the young Brunton of those days a variety of experience, developing his character and opening his scientific eyes to the basic principles of the

mining industry, so that he was ready for the big opportunity when it came, in 1879, at Leadville. There he became associated with his life-long partner, Mr. Frank M. Taylor; together they built the first concentrating mill at Leadville; and, later, erected and controlled several sampling-mills at Aspen, Salt Lake City, and Cripple Creek. This phase of ore-dressing became a specialty to Mr. Brunton, it proved highly profitable to him, and it gave him an opportunity for the exercise of his ingenuity in mechanics, for he invented a contrivance that has become standardized in the sampling of ores. Here we may refer to the other device that carries his name, the compass familiar to mining engineers. During the War this Brunton compass proved valuable in artillery practice, many hundreds having been used advantageously on the battlefields of France.

As has been suggested, the Leadville adventure proved a decisive event in Mr. Brunton's early career. It gave him an opportunity to study the concentrating and sampling of complex ores; moreover, it gave him a chance to examine the ore deposits of a district marked by a remarkable intricacy of geologic structure, and to appreciate the structural relations of orebodies, particularly with regard to faulting and brecciation. In due course he was asked to participate in the flood of litigation that almost submerged the mining industry of Aspen; he became an 'expert' in a series of important apex suits, that is, he was a witness in court. But he did more than that, he directed the work underground that served to uncover the evidence needed by the lawyers. This, of course, gave him an unusual opportunity for becoming familiar with the local geology and of developing his own general knowledge of economic geology. He still continued his engineering work and supervised the driving of the Cowenhoven adit and the sinking of several deep shafts. His reputation at Aspen led to his being called to Butte, where apex litigation on an even bigger scale had been started. There he devised new systems of mine-mapping, and, as consulting engineer to the Anaconda company, planned the exploratory work underground that resulted in the uncovering of large masses of ore. We asked Mr. Brunton, it will be noted, what he thinks of the present system of bringing evidence into Court; he states, as we thought he would, that unbiased testimony is difficult to obtain from witnesses engaged by the litigants themselves and therefore already committed to one side in the dispute. As an example of a better method, he quotes an experience of his own in a Canadian court. In later years Mr. Brunton has lived in Denver, partly on account of his interests in the neighboring mining districts, notably, Cripple Creek, where he served as the engineer in charge of the Roosevelt adit, in the driving of which a pneumatic water-fed hammer-drill, invented by the late George Leyner, a Denver man, first came into prominence. From Denver Mr. Brunton has been called in an advisory capacity to distant places, among them Spain, whither he went in 1903 to advise the Rio Tinto management in regard to the recovery of ore left in their old workings. He has traveled all over the

world, and around it. During the War, of course, he did his share of patriotic work, and it proved to be important. As a member of the Naval Consulting Board he tells us, as others have done, that if the War had lasted a little longer the world would have been astounded at the deadly inventions and lethal devices that would have been brought into action. Another general war is unthinkable for that reason, if for no better one.

The mere record of a man's achievements does not tell the story of his career, for a man can do many things worthy of being chronicled and yet leave no enduring footprints. The best memorial is the one that is transmitted by the living. In the first place, Mr. Brunton has been accepted as a leader among men, having been president of the American Institute of Mining Engineers in 1909-1910. To this mark of distinction we venture to add the statement that in accomplishment and reputation he stands second to no mining engineer in the English-speaking world. He is one of the few mining engineers that have kept away from speculation, promotion, and the other dangerous, if not shady, sides of the mining business; he has preferred to stick to engineering work, rather than make money quickly in devious ways; for that reason his standing is unquestioned and for the same reason he has enjoyed a mental poise highly conducive to real scientific work. He has the ability to concentrate his mental faculties on the problem in hand. By the same token he prefers a few friends rather than common popularity; he sticks to a friend and does not forget an enemy; he is a man of positive character, not a Laodicean. He is a man of progressive and independent ideas; he was one of the first to drive an automobile in Colorado; he has experimented with a score of them since, and was nearly killed in a motor-accident eleven years ago. A friend who has motored thousands of miles with Mr. Brunton says that he is impatient of stupidities or dishonesties of any kind, but is generous to a fault. Like all true students, he is avid for information. On board ship, having seen a friend in conversation with a newly made acquaintance he asked, "Does he know anything?" He remembers his fellow-workers even after many years. When in a club at Waihi, New Zealand, he heard the name of Stansfield mentioned as the manager of the Talisman mine. He recalled the fact that Mr. H. Stansfield had worked for him or with him in Nevada twenty-years earlier and promptly got in touch with him by telephone, this resulting in a visit to the Talisman. One of his oldest friends, who has voyaged afar with him, summarizes his impressions thus: "He is a man of particularly strong likes and dislikes; absolutely true to his convictions; loyal to a degree in his friendships; of exceptional determination in his undertakings and possessed of a deep insight into human nature as well as things material." We confirm that, and to it we add that he is blessed with a sense of humor that lightens the dark places and a geniality that thaws the frozen currents of life. Yes, a man every inch of him, an excellent engineer, and a good citizen. The mining profession is proud of him.

DISCUSSION

Standardization of Mining and Milling Materials

The Editor:

Sir—I was interested in the article on this subject by E. A. Wraight, in your issue of March 12, particularly that portion referring to stamp-battery parts. I think the article gives the impression that the mill operators have taken what the manufacturers have offered in the way of mill-parts with but little effort toward finding out and demanding the material best suited to the purpose. Probably the mill-men have been more at fault in failing to co-operate, each one carrying out his own experiments and investigations without letting others know of the results.

In the article manganese-steel is suggested as a suitable material for shoes. Several attempts have been made to make shoes of manganese-steel, none of them successful. I believe there is difficulty in making manganese-steel castings more than three inches thick. Two sets of five manganese-steel shoes tried in the North Star mill failed because a flat disc the full diameter of the shoe and from 1 to 3 inches thick broke off periodically. Apparently the wearing quality was good apart from this loss by breakage.

At the North Star mine when two 40-stamp mills with 1050-lb. stamps were being operated at 110 drops per minute, the 6-in. diam. 10-stamp cam-shafts, with which the mills were equipped, broke very frequently. One 40-stamp mill broke 11 in one year. The average life was about one year. Shafts made of chrome-nickel steel, vanadium-steel, mild or machinery steel, 'Flyer iron', and forged wrought-iron were tried in an effort to minimize this breakage, and the forged wrought-iron proved to be by far the best material. The fact that nine-tenths of them break under the second or third cam from the free end of the shaft indicates that the factor of safety has but little to do with breakage. The vibration snaps about 5 feet off of a 16-ft. shaft.

It is stated that fractures of stamp-stems are unusual and due to impact, and that stresses are in the direction of the grain. My experience is that fractures are not unusual, and are due to bending where the stem leaves the boss, when the weight of the falling stem lands on one side of the shoe. Practically all breaks occur within a few inches of the top of the boss.

I prefer thin punched steel for battery-screens, not on account of long life, but for freedom from clogging. The cost of the screen is a small item when crushing capacity is involved.

It is stated that a cast-steel battery-frame was erected at the Tightner mine. This is not correct, the frames are of cast-iron, the posts cast in one piece, with cast-iron guide-girts bolted to them: the girts being bored for the base half of the stem-guides, with the guide-caps bolted to the girts. When the two 40-stamp mills at the North Star mine, mentioned previously, were consolidated into one 60-stamp mill with 1500-lb. stamps, cast-iron battery-posts were installed. These were cast in two pieces to make erection easier. Eight-inch H-beams are used for guide-girts, with cast-steel stem-guides bolted to these. When cast-iron is used for battery-posts, there must be enough weight in them to eliminate excessive vibration by virtue of their inertia. Furthermore, it has been found that these solid heavy posts absorb or dampen a large proportion of the vibration in the cam-shafts, practically eliminating breakage.

ARTHUR B. FOOTE.

Grass Valley, California, May 10.

Prospecting

The Editor:

Sir—Upon invitation of a recent editorial in the 'Mining and Scientific Press' I venture to give my ideas upon the future of prospecting. I am a prospector—also a student; in another year I shall be a graduate from one of the mining schools of the North-West—but I shall still be a prospector. When "school" is mentioned the reader doubtless instantly pictures a youth of ordinary college age. But no, my college life has been very intermittent. Two years of war has placed my first and second years of mining engineering far apart. Four years of prospecting and mining preceded my entrance to college, and so, though I am a young man, some practical as well as theoretical experience has been my lot.

At twenty-one a trip for my health to the mountains of a sunny western State introduced me to the gold pan. Fortune led me to the outcrop of a gold-quartz vein just rich enough to keep me digging and return me to robust health. With my partner, also a young man, a few years my senior, we dugged and burrowed. Shaft and tunnel brought specimen ore again and again but never in quantity great enough to assure our fortunes. We tried milling our best with an arrastra run by steam power but the best result was just wages. A mill not adapted to our needs proved a failure. We suspended operations. I came to college to learn of that in which I was interested. My partner prospected elsewhere.

The War came and we both enlisted in the same com-

pany. I returned but he did not. He married a French girl. Upon my return to the States I resumed college work with still the determination to acquire the technical knowledge that would better fit me to be a prospector. "The first step toward knowledge is to be conscious that one is ignorant." The old-time prospector of the hills does not realize his limitations. The successful prospector of the future must realize his. Difficulties not encountered by the old must be met and overcome by the new.

At this the close of my third college year I have leased my mining claims to a company that has agreed to perform extensive development work upon them. To me has been assigned the task of directing this development. I must erect bunk-houses, expose surface croppings of veins, sink shafts, and drive adits. As I know the history of all our prospecting work and know where the best ore occurred it is to be my duty to search for the richest ore-shoots. The summer is before me; if success be mine it will be well; if nature has deposited her precious metals in abundance elsewhere, still it will be well; I shall return to college, finish my course, and return to prospecting better equipped than before.

There is a future for the prospector, but not for the old-time type, especially if he insist on spending most of his time in his cabin dwelling on reminiscences and stories of bonanzas. Placers are fast becoming fewer, veins and lodes are yet to be found. Alaska, in this last respect, is almost untouched; the resources of British Columbia and those of other parts of Canada are open to the American prospector as well as the subject of the King. Fields and opportunities are many but prospecting has yet to be recognized as a profession, worthy of the consideration of a college-trained man.

A college education will not make a prospector, but it will aid substantially in starting one upon intelligent exploration. It is noticeable that few men graduated from mining engineering do any prospecting. One may become an assayer, one a surveyor, another a mine superintendent, and, as frequently occurs, some do not follow mining at all. Prospecting is left to the old-time sourdough and he is fast disappearing.

Prospecting, as systematic search, has, I believe, a future—a big future—but for individual success in following it there appear these inevitable requirements: knowledge of the elements of geology and mineralogy, keen powers of observation, faith in nature, physical endurance, and intense interest and love for the prospecting profession.

WADE V. LEWIS.

Corvallis, Oregon, May 9.

The Editor:

Sir—Regarding the article on this subject appearing in your issue of April 23, I wish to call your attention to one reason why no new mines are being discovered.

I have been out in the mountains much of the time for the past two months, and I find that almost every outcrop has a notice of location on it, many of these locations

dating back to 1916. To my own personal knowledge many of these locators have left this district and have abandoned these claims and do not want them, yet their title will be perpetuated by a bill recently introduced in Congress by Senator Bursum of New Mexico thereby closing these claims to entry by prospectors who would dig and might find something.

Prospectors and miners and mining engineers do not want this measure passed, I feel sure, but they are not the only ones affected. The advertisers in your pages are vitally affected by this class of legislation and many others. The trouble is that so few people realize just how it is actually working in practice.

Luning, Nevada, May 9.

FRANCIS O'BOYLE.

The Editor:

Sir—You give an invitation to chip in; I will take one stack. We all know that the discovery of payable mineral is on the wane. A long experience in prospecting makes me believe that this is due to the conditions the country is in at the present time. There is not a State here in the West that has not been gone over by the prospector; a number of these with easy showings, with outcrops or float gold, have been found. All the mineral areas in the mountains are dotted with prospect-holes, most of which show but little; but they are a great help to the prospector; if they were not there he might be wasting his time; in most cases there was some good reason why these holes were put down, such as the finding of float, good pannings, outcrops, or a favorable looking formation. Such holes are a great help to future prospecting. During the past few years minerals containing tungsten, vanadium, uranium, tin, and numerous others, have come to the front; anyone that follows the business of prospecting ought to turn his attention to these. Most of us know about gold, silver, copper, lead, and the more common minerals. The numerous bodies and veins of iron ore are apt to contain some of these less common minerals. I believe that prospecting in the United States at the present time is brighter than it has been in the past; we have spent too much of our time on little indications—small streaks and the like—where one could only hope to make a small stake. Now most of us are looking for something larger, perhaps for hidden overlooked bodies of the rarer minerals that are being brought to our notice every few months. Some of the old dumps that were made when working for the common minerals are found to contain other valuable mineral nowadays. But we who are making our living with the pick, pan, and lead-pencil are mites compared to the oil-drillers who bring in the new fields. There are thousands of these men who have been drilling for oil for years; the best the majority of them get is a 'duster'—a dry hole. They are the greatest prospectors the world has ever seen. Wild-cat drillers are the ones to take a chance—dreamers and pioneers—maybe a life-time spent with a Keystone or Star rig, rustling money to get their holes down two or three thou-

sand feet; then, one big shot with two hundred quarts of nitro-glycerine, a big puff of white spray, an awful roar, then all quiet. They move to some new field. All of us are playing for a thousand-to-one shot. I have made lots of hundred-to-one shots; I have put in most of my time rustling with the pick and pan (I am no spring chicken), but whenever I find myself with a few dollars I dabble in oil or a duster, just a piker as yet. Many a big deposit of valuable ore has been overlooked in these deep drill-holes; all the analysis that is made of the sludge that is brought up by the bailer is for oil. We hear the cry all around that the country has been prospected to death, but it is not so; the ore is only harder to find. It keeps one rustling to keep going. We need help, but we don't get it; as a rule we are able to work out our own salvation. It is not easy, but it is not hard, as there is always a way to make a raffle. The only help the Government has ever given us has been to ease up on our assessment work; but they wait till the last minute on that, and then there are a lot of kickers. Some that don't know enough or are too lazy to find a prospect, want to locate something that some poor devil of a prospector is trying to hold. The great trouble is we don't last long enough to take everything in. We all have our ups and downs; most of us have had some bad experience—out in bad weather with nothing to eat for weeks at a time except what we could catch—but we always caught it. Then we had our coal-oil-Johnnie days. As a rule we don't worry over our past hardships; but we do think with a thrill of joy of the other days. If I had my life to live over again I believe that I would prospect just the same. The one great fault most of us are guilty of is staying, as they say of the oil prospector, with a dry hole.

Fluorine, New Mexico, May 2.

'Science and Life'

The Editor:

Sir—In a review of Professor Soddy's 'Science and Life', Mr. A. W. Allen undertakes, I think, to strike at religion over the Professor's shoulder, though, at the same time, despite the latter's profound knowledge, he thinks him "turgid". Is it not quite possible that the author has entered a new field, the more so that his life has been given to the study of a specialty? A broad and just view of the spiritual life takes a long time to acquire, and it is entirely possible that the notions on religion set forth in the Professor's book are crude and unfinished like his attempts at writing. I know from various experiences that, as a listener to sermons, when the preacher undertakes to use scientific illustrations, he generally makes a mess of it, and so the author's endeavor to express himself in the spiritual field has no better fate. We admire his profundity in his own line and greatly respect all he says in it, but, as I have also noted in Thomas Edison's attempts along the same line, undigested vagaries may be presented—views due to narrow vision.

So many, in writing on these subjects, fancy it rather grand to have a hit at the "creeds", who, were they asked what they mean by "creed" would have in mind any wind of doctrine. I can assure Mr. Allen that a generation ago when Darwin's views on evolution were pressed to the limit, scientific men were cocksure they were right. Today, many of the older notions, like imperishability of matter, conservation of energy, the imponderable elastic interspatial ether, the transmission of acquired characteristics, are no longer looked upon as finalities.

Science has by no means banished the idea of God's control of the universe, and in the orthodox Christian creed is to be found faith, love, and inspiration. That master-mind of philosophy, Henri Bergson, truly says:

"Many people are hard, narrow and unhappy, and are living without faith, hope and peace, which should be every man's possession, because their minds are imprisoned in a little, narrow, rigid mechanical philosophy, into which they are trying to compress life."

Another assertion, that the idealist is "blind and deaf to science", I take to be an unworthy exaggeration, when we know how the applications of science are known to intelligent men. Certainly, idealists, of all men, should least fear annihilation, nor can one see that they care for science only because of its usefulness in war.

Of course, there are lots of engineers, whose scientific training has left them skeptical, but there are plenty of us who would resent the imputation that we can only talk 'shop'.

L. S. AUSTIN.

Los Angeles, May 8.

The Editor:

Sir—Professor Austin's letter calls for a reply. I do not think, nor did I state, that Professor Soddy is "turgid"; the idea that I quoted extensively from his book for no other reason than "to strike at religion over the Professor's shoulder" is, of course, absurd. The fact has apparently been overlooked that the contribution under discussion was a book review. I, personally, am not the logical target for the Professor's assurance of disbelief in Soddy's views.

The above letter is interesting as illustrating the diversity of opinion that exists on the matter of reviewing. A recent correspondent, who gratuitously referred to the faults of another book under review, objected to adverse comment or correction being made by the reviewer; Professor Austin now objects to the quotation of pertinent matter, seeing in such a method an insidious attempt to strike at something or somebody over the shoulder of the author. So what is the poor reviewer to do?

San Francisco, May 12.

A. W. ALLEN.

Chief Consolidated Shaft

The Editor:

Sir—I beg to inquire if it would be possible for you to publish the following correction to Mr. Arthur B. Parsons' article, appearing in your April 30, 1921, issue,

on sinking No. 2 shaft of the Chief Consolidated Mining Company, Eureka, Utah:

In fairness to the manufacturers of the following drill-machines, the contractor, Walter Fitch, Jr., Company, wishes to state that three types of jackhammers were used in sinking this shaft: The Ingersoll-Rand 'Butterfly'; Sullivan Machinery Co. 'DP-33'; and the Denver Rock Drill 'Waugh Clipper', all of which gave equally good service and satisfaction.

Any favor you can extend in this matter will be appreciated.

WALTER FITCH, JR., COMPANY.

Eureka, Utah, May 13.

Prospecting

The Editor:

Sir—In your issue of April 23, 1921, the article on 'Prospecting, Past and Future' is extremely interesting, particularly to those who have been engaged in prospecting, or closely associated with those directly engaged in this particular branch of the mining industry.

While you describe most of the methods employed, there is one in particular that you have not mentioned, the nearest approach to it being your description of 'costeaning'. The method to which I refer has been responsible for numerous 'strikes' or discoveries of gold-bearing veins and orebodies throughout the Western States.

This method was first developed in the course of pocket-mining in the foothill counties of this State, notably Tuolumne, Calaveras, and Amador. It has been called "panning to locate pockets". Many of your readers, no doubt, are entirely familiar with the method, possibly some are not, and as it is an extremely useful one for the discovery of pockets, bunches, or larger orebodies of gold ore, it may be of assistance to some of them.

Briefly the method is as follows:

Having selected an area on a side-hill that appears likely to contain goldbearing veins, even though they are blind, that is, do not outcrop, the prospector starts near the bottom of the hill, and commences panning (or washing) the loose dirt in the slide, or debris, for gold. If he finds no colors at first, he continues along the general line of a contour of the hill, panning the dirt at every 10 or 20 ft. until he finds colors. At this point he sets up a stake and continues his progress along the line of the contour, panning carefully at intervals of, say, 10 ft., and continues this procedure until he is unable to obtain any further colors when washing the dirt. He then sets up a stake at the last spot at which he was able to obtain colors; he then checks back over the line he has been following to the first stake, to be certain of his results; having assured himself in this particular, he goes up the hillside a matter of 10 or 20 ft., and starts the same procedure, setting up stakes where his colors commence and end. Continuing this method he soon has two rows of stakes, marking lines that converge up the hill, and that will converge sharply, if it is a pocket, or bunch, in the vein; or if they do not converge sharply, and are more

nearly parallel, indicate a more disseminated condition of the gold.

This work is continued up the hill until the panning of the dirt shows no color, which indicates that he is above the vein, and having checked this conclusion by panning inside the area indicated by his stakes, he obtains a line below which the dirt shows color, and above which no colors show, which line indicates the probable course of the vein, and the length of the orebody near the surface.

At this point the usual course is to sink, to find the vein if it is covered, or run a cut for the same purpose. In the case of pockets, or bunches, the pannings will usually show more gold at some point in the line, indicating proximity to the vein, and the remains of the pocket in same, or if the gold is disseminated in the vein, and not concentrated (as in a pocket), the development work can proceed in the manner best suited to local conditions.

If the vein has an outcrop, the matter is simplified, for panning the dirt below the outcrop will show colors of gold, if the vein itself has any gold in it, and the orebodies can be found in this way.

This method has been employed by me in quite a number of instances. The orebodies in the Pamlico mine, near Hawthorne, Nevada, were discovered in this way. Rich float had been found, and although the vein outcropped, the miners were unable to determine where it came from, until I used this method. Fortunately, the dirt below where this vein threw gold from a pocket, or bunch, carried very good values, in fact, from this particular 'fan' we screened (inch openings), and sacked about 100 tons of dirt, which was sent to the mill, and yielded at the rate of about \$110 per ton.

Working upward on this brought us to the vein, which was blind, and which contained the remainder of the pocket, about \$1000. Sinking on this vein showed it to be distinctively a pocket-vein, as the ore occurred in bunches 8 or 10 ft. apart, which bunches might have \$500 or \$15,000 in them. One man took \$15,000 (all in three sacks) on one shift from one of these bunches; some of this ore went \$100 per pound; between the bunches the vein (12 to 24 inches wide) consisted of barren white quartz.

An instance where a failure to use this method lost a fine orebody occurred in the early days of the Goldfield district, at what is known as the Sandstorm mine. This property I had taken under bond for a company operating at Tonopah (the Ohio Tonopah Co.), for which I was in charge.

Having secured the property, I took out a few men and made a camp. We ran some cuts across the big north and south vein that showed on the property. From some of these cuts I obtained good assays, but most of them were low, so I concluded to try the panning method, and to that end took out with me from Tonopah an outfit of screens, pans, a tub for washing, etc., and instructed the foreman to commence the following morning, panning along the side-hill just below the vein to determine

where the gold (if any) occurred. Upon my return to Tonopah that day I found a gentleman there, sent out by my company to take charge of the Goldfield work, as I had quite a crew working in our property at Tonopah, so I explained the situation to him fully, and he went out that evening, and took charge; he immediately discarded the panning method, and started cuts across the vein 50 ft. apart, and carefully sampled the cuts.

This rough diagram shows the situation.

The vein in these cuts showed only small value, except in cut No. 7, from which an assay of about \$60 in gold was obtained. The party started an incline-shaft at this point, but as the material did not hold up in value on sinking (about 10 ft.) he abandoned the work, and transferred the crew to the Atlanta ground, which I also had under option for our company, which then abandoned the Sandstorm.

Later, prospectors came along, and, by panning the surface, found that between cuts No. 7 and No. 8 there was a considerable body of extremely good ore. I understood that they took out about \$150,000 in ore running close to \$200 per ton.

If the panning method had been employed we would have located this orebody with a very small expenditure of time and labor. Other instances might be mentioned, but these convey the idea.

The prospector is a necessity in all mining districts, and is as much a part of the mining business as the miner, the machine-man, the mucker, the foreman, or superintendent; he is the advance-agent blazing the trail, and showing the others where they can work to advantage. To succeed he must be observant, careful in his work, and use a lot of common sense.

The mineral areas have only been scratched; there will be prospecting and mining all through these Western States a thousand years from now, and the optimistic prospector will be in demand then as at present to find new deposits for others to develop and exploit.

More luck to the prospector wherever he is.

San Francisco, May 3.

S. A. KNAPP.

The Editor:

Sir—In your address on 'Prospecting' you touched upon the fact that this calling is not followed to the extent it formerly was. You gave a number of reasons for this. I would like to mention one reason not given by you that while not as broad and far-reaching as those you mentioned does exert a powerful present influence.

It is a fact that since 1917 no claims have lapsed because of legislation excusing the performance of annual

assessment work. In this four years the 'peggers' have been busily at work until practically all parts of the public domain which have the remotest possible mineral value are located.

Up to 1917 probably nearly as many claims lapsed each year as were located. Not but what some claims have been patented each year and many held by annual work, but, speaking generally, the amount of ground open to location and hence attractive to a prospector remained about the same. But since 1917 no valid location, made and completed, has lapsed. There has also accumulated each year a great number of new locations. The result is that the public domain which interests a prospector has become extremely limited. He is not going out into the hills for the very simple reason that he does not care to prospect some one else's ground. You would not if you were in his place. The incentive that if he finds something good it will belong to him is gone, or very largely gone. This condition will continue until there is a clearing time.

It had just about become a settled thing that July 1, 1921, is to be the clearing time. This was the last day for the claim speculators to hold their ground without work. Now some ass in the Senate introduces a bill under the terms of which annual assessment work will be excused for 1921 and 1922. This opens up the subject all fresh. It introduces a new element of uncertainty.

If you can see your way to do so, it seems to me that you could give prospecting a great help by devoting one of your clear editorials to an analysis of the effects of this law and point out that the time has come for it to end. It helps no one but speculators and slackers. I believe that this is the universal opinion of the bona-fide mining people.

E. C. WATSON.

Luning, Nevada, May 9.

[We have written in this sense several times; for example, in our issue of May 14.—EDITOR.]

American Trona Corporation

The Editor:

Sir—Some years ago my partner and I acquired a considerable block of stock in the American Trona Corporation, believing that we had secured a good investment. This belief was grounded largely on the fact that the control of the company lay with the Consolidated Gold Fields of South Africa, Ltd., which we thought would ensure the best management. At that time—1917—the War had stopped importations of potash, and prices on potash, borax, soda-ash, and sodium sulphate, all recoverable from the brine of Searles Lake, were soaring. The company had an unlimited supply of raw material; its railroad to the property was in operation; the necessities of the Government made the production of the various salts a favored industry and we understood that the money was not wanting for development. All the conditions seemed perfect for great money-making.

Yet, month after month production remained small and the management was so dilatory that never during

the War or since has it grown to anything like what was promised. A 'refinery' was built at San Pedro but never operated, and it finally developed that it was built on leased land and was abandoned before being used, a fact that was, so far as I know, never told to the shareholders and only appeared when an enormous charge appeared in the balance-sheet for "Loss on San Pedro Plant, \$403,421.79", along with "Amortization Allowance on Capital Expenditures During the War Period, \$250,000".

The report issued to the shareholders under date of October 31, 1919, ten months after the close of the fiscal year, showed that a gross profit before depreciation, amortization, and obsolescence of about \$1,700,000 was made in 1918. The company was carrying loans of \$1,200,000. The shareholders were informed that a new management was in charge and that greater output was coming.

The report of November 15, 1920, showing results under the "new management", showed that the output of potash salts had fallen from 21,319 tons in 1918 to 13,296 tons in 1919; that a gross profit of about \$1,700,000 had been turned into an operating loss of \$234,631, and a net loss of \$719,524; and that the loans had increased to \$1,950,000. The report gravely states that "additional improvements contemplated should result in *further increased production and reduced costs*". Yet, plant operation cost had increased from \$631,030 in 1918 to \$1,187,229 in 1919 and overhead, interest charges, etc., had increased from \$423,314 to \$426,173, or over one-third of the value of the entire output for expenses other than operating costs.

The change in management, mentioned in the report of October 31, 1919, does not appear to be much of a change according to the list of officers given in the succeeding report, and the board of directors has changed little since 1914. The real and responsible management remains in the Consolidated Gold Fields of South Africa, Ltd., and the shareholders who invested their money on the strength of its supposed good management seem to have little to hope for unless radical changes are made in the handling of the company. To pass the management through a New York office, when it could be much more economically and efficiently handled direct from Trona, seems cumbersome, expensive, and unwise. When will the Gold Fields learn to concentrate and give us some return on our investment? We still believe that a competent, centralized management should produce profits.

San Francisco, May 12.

C. G. FOWLER.

The Gold Reserve

The Editor:

Sir—In your issue of May 14 you state that gold continues to accumulate in the vaults of the Federal Reserve banks and that like Midas we have discovered that one can have too much of it in the sense of medium of exchange; that many of our legislators seem to fear the prospect of being paid in goods from overseas and appear anxious to build a Chinese wall of tariff so as to exclude

imports; that financiers and economists of the less pronounced set recognize the fact that it is to our interest not to collect more of the gold of the world but to encourage commerce with our customers in Europe.

As to the great accumulation of gold in the vaults of the Federal Reserve banks, I think if you will investigate how it is that so much gold is being sent here from all parts of Europe you will find it is money due to the United States for goods sold and some of it for money lent to some of these governments in Europe. Not very long ago the United States Treasury gave out a statement that England had paid the United States \$25,000,000, being the first payment on the loan they made at the time they were in need of silver. It is also reported that England is sending money over to the United States to be prepared to pay the interest due on their loans this year.

It seems to me the accumulation of gold in the Federal Reserve banks is no detriment to the business of the country; on the contrary, it will enable the Federal Reserve banks to lower the discount rate and thus help the general business conditions of the country. When the gold was going out of the Federal Reserve banks and the bankers were warned not to extend any credit except it was absolutely necessary, a great many bankers expressed the opinion that America ought not to make any further loans to Europe but to try to collect some of the money due us.

Europe still owes America a large sum of money and the putting on of a tariff is not done to build a Chinese wall around us, but simply to protect our own industries against the cheap labor of Europe. It seems to me that the late war ought to have been a good lesson to America that America ought to try to build up its own industries so as to be as independent, as much as possible. The more gold we have in the country the stronger we will be financially and the more assistance we may give to our own people.

The Federal Reserve Bank is a good watchdog to see to it that there will be no inflation again. In fact, I can't see how we can have any inflation while all of the European nations are trying their best to make a bid for the world's trade. It was different during the War, when the principal nations were producing but little and had to come to the United States for what they needed.

San Francisco, May 16.

HERMAN ZADIG.

ACCORDING to J. W. A. H. Smit, who contributes an article on the cupellation of gold bullion to 'Rec. Trav. Chim.', the surface and porosity of the cupel are not of such importance as its thermal conductivity. The ratio of lead to copper must be at least 55:1, and may be higher. Heating of the button after iridescence is necessary for commercial samples of gold, and in the case the best ratio of silver to gold is 2:1. The cornets should be well heated both before and after boiling with acid, and it is advisable to roll the buttons into sheets 0.15 mm. thick.

IN THE SAN JUAN REGION OF COLORADO

David W. Brunton: Consulting Engineer

An Interview, by T. A. Rickard

Mr. Brunton, you come of the old stock?

My parents came from Scotland; my father from Selkirk and my mother from Kilmanock. My mother's people are now engaged in coal and fire-clay mining, but in the stormy days of the Reformation the Howies followed the blue and scarlet flag of the Covenanters, and the old Howie homestead at Lochgoin, which has been in continuous possession of the family for 700 years, is now used as a museum and repository of Covenanter relics.

Where and when were you born?

Ayr, Ontario, Canada, in 1849.

What was your early education?

Public school, followed by grammar school, after which I went to Toronto, in 1870, and began engineering work, as was the custom then as an apprentice, under J. C. Bailey, the most prominent engineer in Canada and a member of the English Institution of Civil Engineers.

You come naturally by your engineering career, do you not?

Yes, most of my father's people have been either engineers or army men, some of them having made excellent

records in England, India, and Australia. One of my cousins, recently deceased, J. Dickinson Brunton, was an inventor of stone-dressing machinery and of the tunneling machine, with which he made the preliminary borings for the proposed tunnel under the English Channel.

When did you come to the United States?

In 1873, and in '74 and '75 I took an advanced course in geology and chemistry at the University of Michigan.

Had you any idea at that time of engaging in mining?

Yes, the studies just mentioned were undertaken because after four years experience in civil engineering I became convinced that at that time mining engineering offered a more attractive field.

Did you come directly west from the university?

Yes. The president of the Dakota & San Juan Mining Co. came to Ann Arbor in June 1875, and asked the faculty to recommend a young engineer to go with him to the company's mines in Colorado. They were kind enough to recommend me. I accepted the position and reached Denver on June 20. The company's mines were situated at Mineral Point, in Ouray county, and the near-

est railroad station was Pueblo, 230 miles distant by a recently opened trail, over which all supplies had to be packed.

Did you remain at Mineral Point throughout the winter?

No, the Dakota & San Juan Mining Co. failed to get in sufficient supplies for the winter and we were obliged to come out before the passes were closed. I was fortunate enough to obtain a position as metallurgist for the Hunt, Douglas & Stewart Co. at Georgetown. This proved the beginning of a delightful friendship with James Douglas that lasted throughout his life.

Was the process applied successfully at Georgetown?

It was passing out of the experimental stage and I was fortunate enough to come in just as it was possible to bring the process into profitable operation. The result was that the company immediately began making money, a change that soon attracted the attention of the other mill-owners in the district.

Did you treat any large tonnage by means of this interesting old process?

According to the standards of the present day, the plant was small, having a capacity of 18 or 20 tons per diem. As soon as it was known that the plant was a success, H. Augustus Taylor, the owner of the Clear Creek works, offered me a much larger salary than I was getting, so, after giving the Hunt, Douglas & Stewart people sufficient time to obtain a successor, I moved and built for Mr. Taylor the Clear Creek Reduction Works.

This was a custom plant, I suppose?

Yes, the Clear Creek works consisted of a Krom dry-concentrating mill, which, while somewhat difficult to operate, made an exceedingly clean lead-concentrate, but the middling, which consisted of pyrite and blende, carried a large amount of silver and was unsaleable. The mill that I erected was designed to treat this material, which it did very successfully.

By what method?

While at the Stewart mill I found that when the ore carried a high percentage of zinc and was roasted at a low temperature, chloride of zinc was formed, which acted as an excellent solvent of silver, and in building the Clear Creek works they were designed to use the zinc in the ore and the resulting chloride as a solvent for the silver.

Please describe the process.

The middling from the concentrator was crushed to 60-mesh and roasted at a low temperature, thus producing the maximum amount of silver and zinc chloride, after which the red-hot ore from the furnace was run directly into an agitator, where the silver passed almost immediately into solution. Then the agitator was stopped, and the solid matter given sufficient time to settle, after which the clear liquor was drawn off with a siphon and run over copper plates, which gave us a beautiful crystalline precipitate of silver, the dissolved copper being recovered on scrap-iron.

That is very interesting. Did you remain long at Georgetown?

About a year and a half; then I went to Caribou, also in Colorado, to build a similar mill for the Native Silver Mining Co.

You used exactly the same process and also successfully?

Yes, and very successfully; but one winter at Caribou was enough for me. The mill was covered with snow for four months, so that nothing was visible but the ventilator and the smoke-stack, and we had to tunnel through the snow from the assay and general offices to the mill.

So you sought a change, and whither did you go?

I had an offer to go to Silver Peak, Nevada,* as engineer to build a similar mill to the ones at Caribou and Georgetown. After being there for about a year, the manager was taken ill and recommended that I be appointed his successor.

What company was that?

The Silver Peak Mines company, which was then controlled by John I. Blair of Blairstown, New Jersey.

What sort of an extraction did you get by the use of this leaching process and what was the approximate cost per ton, if you can recall it?

Comparing the assay-value of the ore with the amount in the tailing, the recovery would figure 95% to 97%, but, of-course, that did not include the loss by volatilization during roasting, so that the net result was probably in the neighborhood of 93% to 94%. At Silver Peak the milling cost was unusually low owing to the fact that we had an enormous deposit of salt a stone's throw from the mill.

If you cannot recall the actual cost, and that isn't at all surprising considering how long ago it was, perhaps you can recall the average grade of the ore, which would show how rich it had to be in order to conduct operations at a profit.

The Silver Peak Mines company owned two groups of claims, one nine miles from the mill and carrying gold ore, the other four miles from the plant and carrying silver only. The new mill was built to treat the silver ores, which had an average yield of not far from 50 oz. per ton. The silver mines were soon exhausted, and after this we turned our attention to the gold mines, which had at one time been operated by Prof. Clayton.

What were his initials—J. E. Clayton?

Yes, Prof. Joshua E. Clayton.

He was a notable figure in mining in those days.

Yes. Further prospecting and development on the gold mines brought to light better ore than Prof. Clayton had been treating, with the result that the gold mines immediately became very profitable, the average recovery from the ore milled being about \$12.50 per ton.

You were using stamp-milling and amalgamation?

We were using the old-fashioned stamp-mill with bat-

tery and copper-plate amalgamation, the same as was used by Clayton. John I. Blair, who was known as an exceedingly grasping multi-millionaire, became so excited over the profitable operation of the mines that he tried to

Long enough to freeze them out?

No, he never succeeded in freezing them out, but his heirs sold the mines to the present Pittsburgh Silver Peak Mining Co.

HAULING ORE BY A 16-MULE TEAM FROM THE SILVER PEAK MINE TO THE MILL IN 1879

buy out the minority stockholders. They, of course, under the circumstances, refused to sell, whereupon Mr. Blair told them that if they did not sell he would shut

Now we will return to you. When did you quit?

In September 1879, when Mr. Blair sent orders to me to close the mines down, pay all the bills, and put a com-

THE SILVER PEAK MILL IN 1878

the mines and keep them shut-down as long as he lived, which was exactly what he did!

How long did the old rascal live?

For a long time, but I do not remember the date of his death.

petent watchman in charge. Just at this time the discoveries at Leadville were attracting the attention of everyone, and after fulfilling Blair's orders and seeing that everything was in shape for a permanent shut-down I went to Leadville, traveling by sled from Georgetown,

arriving at Leadville early in the winter of 1879.

Leadville, I presume, at that time was booming?

It was indeed. At that time Leadville was the Mecca for adventurers of all kinds, and everything was crude; ore was being shipped as rapidly as transportation facilities would permit, or as fast as it was treated by small local smelters. In the spring of 1880 a strike occurred, but it was of short duration. After that Leadville continued to grow with mushroom-like rapidity. One of the first things I noticed was that the surface ore, especially on Carbonate and Fryer hills, carried little or no lead and could be treated readily by what was known as the Washoe process, a method for extracting silver developed on the Comstock. F. M. Taylor and I built a mill in California gulch for treating this material, which we operated successfully for a number of years. After the operations of the mill were so stabilized as to require little metallurgical attention, I began engineering work for different companies in Leadville, the first of them being the Robert E. Lee, and subsequently for the Duncan, Wolftone, A. Y. & Minnie, and the Dinero. Later I was made manager of the Colonel Sellers mine, which at that time had the largest output of any mine in the district.

What was the character of that output?

The ores near the surface were argentiferous galena, but as depth was gained a considerable percentage of blende began to appear and soon the amount of it became so great that the zinc penalty imposed by the smelters materially interfered with our profits. After some study and experimenting, I designed and erected a mill to separate the galena and blende, which was completely successful.

What was the nature of your process?

Wet concentration by means of high-speed jigs and Frue vanners.

What sort of a product did you make?

The jigs made an excellent lead product with a very small tailing loss, but owing to the large amount of water flowing over them the vanners were not so successful. To remedy this, I designed a dewatering system by which we could put the pulp on the vanners at any degree of density we desired. This brought the recovery on the Frue vanners up nearly to that of the jigs.

Can you recall the percentages?

No, I can not. The A. Y. & Minnie mine was contiguous to the Colonel Sellers, and in mining they followed through much the same cycle as the Sellers. As soon as Messrs. Graham and Guggenheim, who owned the A. Y. & Minnie, knew of the success of the process for separating blende and galena on the Colonel Sellers, they asked me to build a similar mill for them, which I was glad to do, and as the ores were identical the mill was a complete success.

If I recall correctly, the connection of Meyer Guggenheim with the A. Y. & Minnie was the foundation of the Guggenheim dynasty in the United States?

I believe so. At that time Benjamin Guggenheim was

in the office of the A. Y. & Minnie and later he was persuaded by E. S. Holden to invest some of his father's money in a smelter at Denver. This was the first link in the chain of Guggenheim smelters, which now reaches across the United States, Mexico, and Chile.

So you had an interesting experience with the treatment of the complex silver-lead-zinc ores?

We had sense enough to know that the blende, which was not saleable then, would some day be valuable, and we built large log cribs on the side-hill, in which all of the blende separated from the galena in both the Colonel Sellers and the A. Y. & Minnie ores, was stored. It was many years before this blende-concentrate became marketable, but ultimately it became valuable and was sold at remunerative prices to the Empire Zinc Company.

How long did you remain at Leadville?

Until 1886. At this time the mines in Aspen had come into prominence and the dispute between the different owners had culminated in a number of important apex-sideline lawsuits. As I had acted as engineer for the law firm of Patterson & Thomas in a number of mining suits, they asked me to go over to Aspen and assist them in their litigation. The suits were tried in the Federal Court at Denver, and after I had been on the witness stand all day I was asked to come to the attorneys' office that night. When I entered the room in fear and trembling, expecting censure for sins of omission or commission on the stand, I found the sideline mine-owners of the district all there. D. R. C. Brown, who acted as spokesman of the party, said, "We want you to come over to Aspen and take charge of our work". I replied that I had a comfortable home and a good position at Leadville, and did not want to move. The spokesman for the owners then said, "How much money do you want to sell out at Leadville and move to Aspen?" I mentioned a sum that I thought large enough to block proceedings, and the reply was, "You can't come too soon!"

So you agreed to sell out?

Their acceptance of my offer settled the matter, and as soon as I could arrange my own affairs and those of the Colonel Sellers I moved from Leadville to Aspen.

Were you married at this time?

Yes, I was married in 1885 to Miss Katharine Kemble of Kingston, New York, and at this time we were living very comfortably at Leadville and had one son.

So you moved to Aspen?

Yes. The apex-sideline suits involved mines on both sides of the Roaring Fork and for the first few years my work was confined to developing the mines for both economic and legal purposes, and handling the details of these suits. As soon as they were settled I was made manager of the Della S., the Free Silver, and the J. C. Johnson mines. On the Smuggler Mountain side of the district the difficulty of hauling the ore down the mountain and the depth from which water had to be raised made a more economical method of mining necessary, and the Cowenhoven adit was started and driven to afford

TIMBER FRAMED FOR USE IN THE COWENHOVEN TUNNEL

ELECTRIC HOIST AT THE FREE SILVER MINE, AT ASPEN, IN 1895

cheap drainage, transportation, and ventilation for the mines of Smuggler Mountain and beyond.

What was the length and size of this adit?

The Cowenhoven adit had a length of two and a half miles, a width of 7 ft. 8 in., and a height of 7 ft. It was double-tracked throughout, and between the tracks was a covered waterway 12 in. deep and 16 in. wide.

Do you recall the cost of building this adit?

The cost of construction varied greatly according to the character of the rock through which the adit was being driven; it averaged about \$20 per foot. At one point, for several hundred feet, we drove through soft porphyry, which crushed the timbers almost as fast as they could be put in place. At other points we ran through large open caves filled with dolomitic sand and broken rock necessitating the use of driven spiling. The weight on this spiling was so great that under the old-fashioned tail-block system of driving, the planks were battered and split before we could drive them into place, and I devised a new method of holding spiling in place, best described as a swinging false set.

Will you kindly describe it in more detail?

Under the old system the spiling was held in place by a block between the new plank that was being driven into place and the spiling on the last completed set. Under the new system no tail-block was used, but instead a light steel arched cap was pivoted over the sill last put into place and on this cap rested the forward end of the spiling that was being driven. The spiling was 3 by 6-in. plank cut to a chisel-edge. The false set carried the forward ends of the spiling and they were driven into the face, the forward movement of the false set being controlled by means of screw supports.*

Did you use square sets?

We did at first, but soon found that square sets would not stand the pressure and we were obliged to replace them by arched sets such as are used in railroad tunnels. In some places where the adit ran through crushed shale or softened porphyry the sills were pushed up so that we were obliged to replace them with inverted arches.

I suppose today, if you were to construct a similar adit in such yielding ground, you would use reinforced concrete?

Yes, provided that the probable life of the ore deposit were sufficient to justify the expense.

You will recall, I expect, the early introduction of electricity in mining operations at Aspen. That must have some historic value.

I believe that electricity was first used underground in Aspen in 1888, when a 10-hp. electric hoist was placed in the Veteran tunnel by W. B. Devereux. When the ore deposits of Smuggler mountain were found to extend well below the Cowenhoven adit, in order to sink inclines at distances of from one to two miles from the mouth of the

tunnel, electric hoisting was the evident solution of the problem, and all of the mines operating below the adit were equipped with electric hoists. Later, when the inclines below the Cowenhoven adit attained considerable depth, it was considered advisable to sink a shaft from the surface not far from the mouth of the tunnel, and the Free Silver shaft was started. This shaft had a depth of 1200 ft. and its pumps a capacity of 4000 gal. per minute. The electric hoist, which I designed for it, was for many years featured in the General Electric Co.'s catalogues as the largest electric hoist in the world, but compared with some of the electric hoisting-plants now installed in this country and South Africa it was a very small affair.

Mr. Brunton, I know that you were connected in a professional capacity with important operations at Butte. When did that connection begin?

In 1890, while I was still connected with the mines at Aspen, Messrs. Patterson & Thomas were appointed attorneys for the Little Darling mine, which at that time was engaged in apex-sideline litigation with the Blue Bird mine near Butte, and they made the point to the Aspen mine-owners that the Little Darling was a sideline mine and that some points in that contest were so similar to those at Aspen that the legal decision in the Butte case might have an influence on the Aspen case, in view of which the Aspen owners consented to my going to Butte and taking engineering charge of the litigation.

Who owned the Darling mine?

James Murray, who was a great friend of Marcus Daly. This suit never came to trial because we forced the Blue Bird owners into an untenable position and they were obliged to buy the Little Darling.

Who was running the Blue Bird then? Was it William Keller?

No, Robert Boraem was manager and William Keller was engineer. After the transfer Mr. Daly, who had been following the progress of the suit with a good deal of interest, asked me to become consulting engineer for him, which I did, and remained with him until he sold the Anaconda mines to the Amalgamated Copper Company.

So you again became a participant in apex suits?

Yes, but at first the work consisted almost wholly of studies in economic geology, and as Daly was continually branching out and buying new properties, the amount of work involved was much greater than any one engineer could possibly take care of. I mentioned this to Mr. Daly and he immediately said, "There's no strings on ye", which meant that I was free to make whatever arrangements I saw fit, and I then engaged Horace V. Winchell as geologist. The importance and value of the geological work carried on was so manifest that quite a staff of engineers and geologists was soon employed under Mr. Winchell's direction. At this time litigation was impending between the Daly and Clark interests in Butte, which later culminated in the Colusa-Parrot v. Anaconda suit.

*A fully illustrated description is given in Proc. Inst. C. E., 1898, pp. 289-306.

This was the beginning, I presume, of the long series of litigations in Montana and also of the political warfare between the opposing factions?

Yes.

I would like to ask you to what extent the work done in connection with the litigation led to the discovery of orebodies, that is to say, to what extent it was economically valuable to the mining district.

It was of extraordinary value to the mining district, because it was during the progress of our studies that we gained the first inkling of the complicated fault-systems in Butte, the unraveling of which has enormously cheapened development and added greatly to the amount of recoverable ore. The economic value of this geological work was not at first well understood by the superintendents of the different mines, but later, in order to fully utilize the work of the geologists, we devised a new system of mine-mapping that has been highly developed by the geological staff at the mines, so that today they have undoubtedly the best and most useful set of geological mine-maps in existence.

To whom would you give credit for the development of this interesting system of mine-mapping?

The beginnings of this system I devised at Aspen to enable us to follow and locate the faulted portions of the different veins. When we came to apply it to Butte this system had to be greatly elaborated and has been still further developed and improved by Mr. Winchell and his successor, Reno Sales.

What is the principle underlying this system?

The surveyors make the ordinary mine-map, from which the geologists take off individual level-sheets, copies of which they carry into the mine and place the geology on the sides of the openings exactly as exposed in the workings. Then, for the working-map in the office, we take a tracing on vellum of each individual level and place these sheets in what might be termed a large loose-leaf holder so that they occupy the exact position with

relation to each other that they do in the mine. On each individual sheet there is platted not only the workings but the geology, and as you can read through about two or three sheets of vellum it is easy to see the relation of the workings, faults, and orebodies to each other. Under the old system the mine superintendents and foremen took but little interest in the geological maps, but as soon as the new system was introduced we found them spending a considerable portion of their time each day studying these maps and drawing inferences from them.

The use of this transparent vellum is comparable to the information obtainable from the model of a mine, by visualizing the relations between the workings and the discoveries of ore to each other, is it not?

Yes, but I think that maps of this kind are more convenient and useful than any model I have ever seen. The next step was for the mine superintendents, and even the foremen, to ask the geologists to go with them through the mines and discuss the exposures at each point where there was a difference of opinion, so that in a short time after this system was put into use both superintendents and foremen were working in close harmony with the geologists.*

Now, Mr. Brunton, I want to put a delicate question. I would like your opinion as one better versed in mining litigation than any man, with the exception of Dr. Raymond if he were alive, as to the system whereby geological evidence is brought before the Court. I would like to ask you to look back upon your experience and to tell me, and tell our readers, whether you can suggest a better method of making the Court acquainted with the technical aspects of apex controversies.

The best method of placing actual mine conditions before a judge or jury is by some graphic method of visualization. Verbal descriptions of mine-workings convey little or nothing to a man who has never been under-

*A full description was published in Trans. A. I. M. E., July 1905.

ground. In some suits the attorneys deliberately challenge and reject from the jury a man who knows anything about mining, under the plea that he is probably already biased for or against the apex-sideline law, so that such juries are necessarily composed of men unacquainted with mining. As these men know nothing about mining law, and care less, they generally decide a suit in accordance with their sympathies, which are always with the side that they understand best; hence the necessity in a mining suit for introducing models, colored maps, and anything that will enable the jury to visualize conditions better than they can from verbal descriptions.

But most suits nowadays come before the Federal courts and are not tried before a jury, but before a judge.

What I wanted to ask you particularly was whether the method of bringing evidence before the judge could not better be done by so-called experts or specialists not in the employ of the litigants but engaged by the Courts—even if secured by the Court under an agreement between the litigants?

I believe that such a method would be very much preferable to the present one, for the reason that it would then be possible to obtain unbiased testimony from the experts. While a witness is under oath he, of course, is obliged to describe conditions exactly as they occur, but his deductions from such observations are often biased by the opinion and attitude of his associates, and we all know that during the preparation of a lawsuit the men become enthused with their particular views and the mental attitude of one witness reacts on his fellows, and by the time the case is tried the experts are usually almost as partisan as the attorneys.

By the way, you have had some experience as an expert witness in British Columbia. Have they not a system there that is different from ours?

I have not taken part in any Canadian mining lawsuits, but, as engineer for the sub-contractor on the Canadian Pacific five-mile tunnel through the Selkirks at Rogers Pass, I was dragged into the litigation between my employers and the contractors. Many geological questions were involved in these suits and both sides freely availed themselves of the best geological talent in this country and in Canada, so that the testimony in many ways resembled that in an apex-sideline mining suit. During the trials I was particularly struck with the dignity and expedition with which these cases were conducted. Waste of time, through baiting of witnesses and wrangling between attorneys, was absolutely prohibited, and the judge had two assessors with him on the bench as advisors. These men were selected by the judge in chambers, were paid by the losing side, and the judge conferred and consulted with them on all technical questions arising during the trial. In both of these suits, the men selected to act as assessors were well qualified for the position, one of them being the most prominent civil engineer in the Province, and the other the largest railway contractor.

I remember you told us how you first became associated

with Mr. Taylor. I know from my residence in the West that Taylor & Brunton is a firm that has been associated for several decades with the sampling of ores. Will you please tell us how you first got into this business and something about the technique of it, if the secrets of the business may be divulged at this late date?

When I was engineer for H. Augustus Taylor in 1876-'77, his son, my present partner, Frank M. Taylor, was acting as business agent for his father, and the old gentleman always insisted that Frank and I should go into partnership. He said the combination would be an advantageous one for both of us, and talked so much about it that we finally followed his advice.

That was in what year?

That was in 1880.

How did you get into the sampling business?

Through testing sampling machines and methods for the smelters. In lead smelting it is more economical to obtain a correct smelting mixture by a judicious mixing of ore than by adding dead flux. If these ores are obtained by purchase from different owners it is important that their exact composition should be determined before mixing them on the bedding-floor, therefore, coincident with the growth of lead smelting in this country came the demand for more accurate sampling. The old-fashioned methods such as the divided chute, whistle-spout, split-shovel, riffle-board, and Cornish quartering, no longer sufficed, and a more speedy and exact method became almost a necessity. Various mechanical devices were invented for this purpose, and I was often called by the smelting companies to pass upon their accuracy, but always found them deficient in some important particular. This was hardly to be wondered at when we consider that the same machine must give accurate results whether the ore passing through it be rich or poor, wet or dry, coarse or fine. Later on, in thinking over the sampling problem, the idea occurred to me, why not make a division of time, which is something that can be divided with exactitude and to infinity. At first I was unable to tie this idea to any workable mechanical contrivance, but later succeeded in doing so, the result being the present oscillating time sampler, which is acknowledged by everyone to give absolutely accurate results independent of the physical condition of the ore or the bias of the operator.

You are referring to the taking of the entire stream of ore for a fractional portion of the time?

Yes. I was fortunate enough to obtain a basic patent on the device for doing this, but other methods of obtaining the same result have since been devised, the most successful being the one invented by H. A. Vezin. Soon after the introduction of the Vezin type of sampler, an ingenious but unscrupulous engineer, who unfortunately is still at large, devised a means of interfering with its accuracy. Vezin was a man of unusual ability and sterling honesty, and when he found that the device on which he had spent so much time and study could be

THE BRUNTON OSCILLATING TIME-SAMPLER

tortured into giving an incorrect sample, it almost broke his heart.

What is the method?

The intake spout on the Vezin type of sampler is in the form of a sector, and unless its cutting edges are exactly radial the proportion of sample taken from all parts of the falling stream will not be equal, consequently it is only necessary to arrange the delivery spout so that the portion of the stream carrying the greatest proportion of coarse ore (which is usually the lowest grade) will fall through that part of the deformed sector which will take the largest proportion of sample. As the radial cutting edges on this type of sampler are of considerable length, their deformation by accident or design is extremely easy. A series of tests made at Cripple Creek shows that a slight displacement of the radial cutting edges with a conveniently arranged delivery spout would account for a difference of 10% in the sample.

Is it possible to interfere with the accuracy of the Brunton time-sampler in the same way?

No, the parallel cutting edges on the oscillator are so short and stiff that it is impossible to do anything that would interfere with the accuracy of the sample. We are so firmly convinced of this that we do not hesitate to allow men in our mills, who have interests in leases, to sample their own ore.*

Your name is also associated with the well-known pocket transit. What led you to invent this useful instrument?

When I first began the examining of mines an engineer was obliged to carry a small satchel full of instruments; I rebelled at carrying such a load and endeavored to devise a single instrument that would perform all the operations necessary in ordinary mine examinations and

reconnaissance surveys. At first the results were disappointing, but, by continued change and improvement, I succeeded finally in producing an instrument that was in every way satisfactory. At that time I had no thought of selling or patenting it, but simply had it made for my own personal convenience, but I soon found every time I went into a mine that the superintendent or manager would say, "Where did you get that instrument? I want one", and when I returned to Denver I would be obliged to order one, two, or three of these instruments for them. By and by the demand became so great that I patented it, in 1904, and made arrangements for its manufacture.

When did you manufacture your first instrument and who are manufacturing them now?

My first two or three instruments were made by Negretti & Zambra of London, in 1900 and 1901, but the length of time required to carry on correspondence about desired improvements and changes was so great that I finally arranged for the manufacture of the instrument with William Ainsworth & Son of Denver, who are still the sole manufacturers under all of my patents.

I understand that the instrument was used during the War.

The engineers who went into the Army naturally took their pocket-transits with them, and they proved so useful at the front that we had a steady flow of orders both from the Government and individual officers, and the military type of my instrument, which carries in addition to the usual graduated circle, a radium dial for night-surveying, and an alidade attachment for plane-table work, has been adopted now as standard equipment in the United States army. The military surveying instruments are all graduated from zero to 360° counter-clock so as to read azimuths directly from the north end of the needle, instead of being graduated from zero to 90° in quadrants as usually ordered by mining and civil engineers. There is much less opportunity for error in recording surveys by azimuths than by courses, and I

*For full illustrated description see 'Theory and Practice of Ore Sampling', Trans. A. I. M. E., 1895, and 'Modern Practice of Sampling', Trans. A. I. M. E., 1909. Also Bureau of Mines technical paper No. 86, on 'Sampling Conditions in the West', by T. R. Woodbridge.

would unhesitatingly recommend that all engineers adopt the military system. During the War, at the request of the military authorities, a slight variation of the standard pocket-compass was designed for use as a fire-control instrument for non-portable machine-guns. For this purpose the Government purchased 1500 of them. These instruments, of course, were graduated under the French mil system.

What is that?

Our system of dividing the circle into 360° means practically nothing, as we might just as well have divided the circle into 200° or 400°. A French military officer, some time before the War, conceived the idea of dividing the circle into 6400 parts, which he calls mils, the peculiarity of a mil being that it is approximately one-thousandth of the radius, consequently a deflection of one mil at 1000 metres distance would mean one metre; two mils, two metres; etc., thereby enabling many problems relating to gun-pointing to be performed mentally and with ease and rapidity. In fact, this simple but brilliant invention has proven an important factor in the wonderful efficiency of French field-artillery.

When did you become interested in Cripple Creek?

I went to Cripple Creek in 1894, but we did not build our first sampling-mill there until 1896, the second and larger plant being built in 1901. Later, when the mines of Cripple Creek became so deep that the expense of individual pumping became prohibitive and some central system of drainage became necessary, the Mine-Owners Association asked me to study the problem and decide on a method to be employed. Topographic surveys of the district and a study of the amount of water coming into the different mines showed that the most economical method of drainage would be by driving a drainage adit, and my recommendations were made accordingly.

What was this adit called and what is its length and the amount of water tapped?

This drainage adit was promptly christened the Roosevelt Tunnel, by which name it is generally known. Its length from the portal to the principal watercourse in the ore-zone is 17,200 ft. The amount of water flowing from the tunnel when this watercourse was first tapped was 12,000 gal. per minute, which has gradually diminished until today the flow is less than 1000 gal. per minute. The contractors for this tunnel elected to use the old Leyner rock-drill, and later Mr. Leyner sent them up a new small pneumatic water-feed hammer-drill for straightening out the sides of the bore and removing inequalities from the floor. To the astonishment of everyone, this little hammer-drill did faster work than the big piston-drills, and it was clear that a new mining tool had been developed which marked a great forward stride in rock-drilling machinery. It took some time for me to persuade my old friend William L. Saunders, president of the Ingersoll-Rand company, that a new drill had been invented which promised to revolutionize the rock-drill industry, but at last he came out to Denver and after an examination of the Leyner hammer-drill did

not rest until he had purchased all of Mr. Leyner's patents and engaged him as consulting engineer for a five-year period. The Ingersoll-Rand company immediately used their vast resources to improve and perfect this drill until today machines are being produced under this system that will drill 12 inches per minute in hard granite.

Cripple Creek is pretty quiet now, is it not?

Cripple Creek, of course, is not as lively now as it was in 1900, when it had a yearly output of \$18,000,000, but a district which has produced \$315,000,000 in 29 years and is still producing at the rate of \$5,000,000 per annum is very far from being defunct.

Did you take part in apex litigation in Cripple Creek?

Yes, as consulting engineer for the Golden Cycle company, during their litigation with the Vindicator. This suit, however, never came to trial, as it was settled by a consolidation of the two companies. One of the models built for this suit, however, is worthy of mention. It became probable that an important factor in the case would be the showing in the discovery shaft of the Golden Cycle mine. Just how to present the facts shown in that opening to the jury puzzled me for some time, but I finally hit upon a plan that proved eminently successful. The Natural History museum in Denver had brought out an expert from New York to make rocky backgrounds for the different animal groups in the museum; these were so beautifully done that anyone interested in geology could not help noticing them. Just at the time this expert had completed his work and was about to return to New York, it occurred to me to ask him if he could not reproduce the discovery shaft of the Golden Cycle, to which he agreed, and in two months made a model that was an absolute reproduction of the discovery shaft in form, texture, and color. I think this method of showing conditions can be used successfully in many cases. The gentlemen on the opposite side of the case, when once the suit was settled, were quick to acknowledge that this reproduction of the shaft would have meant their certain defeat had the case come into court.

Are your sons mining engineers?

Only one of my sons elected to study mining engineering, and, on the completion of his sophomore year at the Colorado School of Mines, he went on a surveying trip during the summer to North Park, where he became enthused over pure-bred stock-raising and absolutely refused to go back to college. There was nothing to do but to let him follow his bent, in which I was much disappointed; but perhaps it is all for the best, as Jack is now owner of the Glendale stock-farm and has made a greater success in raising pure-bred polled Herefords than he was likely to do in mining engineering. My oldest son, Fred, was graduated as metallurgical engineer from McGill University and is now in Mexico. My youngest son, Harold, graduated with honors as mechanical engineer at the University of Colorado and is engineer for the Plains Iron Works of Denver. My

son-in-law, G. B. Shanklin, is an electrical engineer engaged in research work for the General Electric Company.

How do you compare the facilities for education in your day with those that your sons have been able to obtain?

The engineering colleges of today are so far ahead of their predecessors of forty-five years ago in personnel, apparatus, and equipment that present-day students have opportunities both in college and after leaving it that we old-timers never dreamed of. When I came West, mining engineers were scarce, and, worse than that, American mining engineers were not considered to be in the same class with the German. It took many years to convince the general public that the American

engineers in Mexico and South America, I found the Spanish miner to be an exceedingly cleanly, skilful, and industrious individual. Of course, he has some racial characteristics, and among them is a dislike to being bossed. Out of this, and some other traits, has grown the curious and far from inconvenient system of working now in vogue at many of the mines. Guided by the unions and local custom, there has been established in each district what constitutes a standard day's work in all surface and underground occupations, and when this amount of work is performed the men receive from their foreman a ticket that they cash at the paymaster's window on their way home. This plan gives them an unusual degree of

PHOENICIAN IDOLS FOUND IN AN OLD STOPE AT RIO TINTO

engineers were better qualified to handle conditions in the West than foreigners.

I understand that you have made a number of trips to Spain. How were you impressed with Spanish mines and miners?

Spain is a country of wonderful mineral resources, and although many of the mines have been worked since prehistoric times, they are still far from being exhausted. Some of the largest producing mines of today were worked by the Phoenicians and furnished copper for the bronze that went into Solomon's temple, and have since been worked successively by Roman, Moorish, Spanish, and English owners. In early times, before the days of explosives, mining operations were necessarily slow and mines had some chance of longevity, but in recent years many of the oldest Spanish mines have been subjected to the most intensive attacks with modern air-drills and steam-shovels without seriously decreasing their reserves. Contrary to what I was led to expect from my experi-

ENGINEERS EXAMINING A ROMAN AMPHORA FOUND IN THE RIO TINTO WORKINGS. LEFT TO RIGHT: C. H. MACNUTT, W. A. CARLYLE, R. E. PALMER, AND D. W. BRUNTON.

personal freedom, as it allows them to begin work when they choose and they are free to quit whenever the day's stint is accomplished. Under this system most of the men begin work about 6 a.m. and by 1 p.m. the more energetic and skilful have completed their tasks and begin moving homeward. By 4 p.m. the mines are practically emptied.

In what particular work were you engaged while in Spain?

Consultation work for the Rio Tinto company. They especially wanted me to study and devise some means of recovering the enormous tonnage of ore left behind in the floors and pillars of one of their largest mines after it had been worked to the limit by the pillar-and-stall method. The immense size and great depth of this deposit, coupled with the prospect of self-ignition when large masses were allowed to move or slide, precluded all

possibility of using any of the established systems of mining. After a great amount of study, consultation, and experiment, a method was finally devised that has proven safe, economical, and completely successful in recovering all of the ore from these old workings.

Will you describe the system briefly?

It is a direct replacement system, taking full advantage of both surface and underground conditions as well as the habits and skill of the Spanish miners, but an intelligible description would require drawings that would be scarcely worth while, as I do not believe that such a complicated and exacting system could be successfully employed anywhere else on earth.

You did all that you could during the War, I am sure.

In what particular service were you engaged?

When the United States entered the War, the different scientific and technical societies in this country held a series of meetings to decide what they could do to assist the Government, the result of which was that each society elected two members to represent them on a central body to be known as the War Committee of Technical Societies. Edmund B. Kirby and I were chosen to represent the American Institute of Mining Engineers, and H. W. Buck of New York was elected chairman of this committee. Shortly afterward pressure of work entailed by some large Government contracts, which his firm had received, compelled Mr. Buck's resignation. I was elected his successor and served in that capacity throughout the War. The War Committee soon found that with the various societies behind them they had an abundance of scientific and technical assistance but were grievously short of funds. The Naval Consulting Board, which had been created for some time, was in exactly the opposite position. Its members were all prominent busy men, many of them engaged in Government work, and they had little time to devote to the incoming flood of war inventions submitted to the Government, and after several consultations the War Committee of Technical Societies decided to co-operate with the Naval Consulting Board. This gave us offices, money, clerical and stenographic help, Government printing facilities, and a postal frank, by means of which we were able to accomplish much more than our original program contemplated. Later, I was appointed by Secretary Daniels a member of the Naval Consulting Board, and about the same time I was made a member of the Inventions Section, Plans Division, of the General Staff of the Army. *That was fine.*

The work assigned to the Naval Consulting Board, Inventions Section of the Army, and the War Committee of Technical Societies was the consideration of inventions submitted to the Government for use in the War. The great interest that the inventors and scientific men of the country took in the contest soon brought such an avalanche of ideas and inventions that our New York office had to be enlarged, and later, the Government asked that we move our headquarters to Washington, where we were given ample room and every facility for work.

Something like 135,000 ideas, suggestions, and inventions were submitted. The bulk of these, of course, were useless, but it took a vast amount of work and study to separate the few grains of wheat from the mass of chaff. Even among the meritorious inventions received, few were sufficiently perfected for immediate utilization, and a great amount of time and effort were required to develop and test them preparatory to manufacture. The French and English also had their Inventions Boards, which were in existence, of course, much longer than ours, and they also found that to develop, test, and put a new invention into quantitative production required not far from a year.

Were any of the suggestions or inventions put to fruitful use during the War?

Yes, some of them were; and had the War continued six months or a year longer some very important inventions would have come into general use at the front that would have done much toward convincing the Germans that General Sherman's description of war was correct. One of the most important results of the activities of the Naval Consulting Board has been the adoption of a plan for building a large experimental machine-shop and research laboratory for the Navy, on the banks of the Potomac, a few miles below Washington. For this purpose \$2,000,000 has been appropriated, government land set apart on which to build, and contracts let for the entire plant. This experimental shop and laboratory will be used not only for research work of all kinds connected with the Navy, but new inventions submitted from any source for naval use will be examined and tested and those which are found to possess sufficient merit will be developed, perfected, and carried forward to a point where they will be put into immediate use or held ready for quantity production in case this country should at any time be unfortunate enough to be forced into another war.

THE copper output of Alaska in 1919 was 47,220,771 lb., valued at \$8,783,063, states a U. S. Geological Survey report. This is less than the output in 1918, which was 69,224,951 lb., valued at \$17,098,563. During the year, 11 copper mines were operated, compared with 17 in 1918. Of these mines, 3 are in the Ketchikan district, 5 in the Prince William Sound district, and 3 in the Chitina district. The curtailment of copper mining was due to the fall in the price of copper and the uncertainty of the market. Throughout the War the small operator was hampered by lack of shipping to transport his ore and of smelters to reduce it, conditions that blocked the development of a number of properties and discouraged the copper-mining industry. Largely for these reasons there has been relatively little prospecting for copper during the last few years. Should freight-rates decrease or the price of copper go up, many small mines would resume operations and the larger low-grade orebodies would be developed. The average copper content of the ores mined in 1919 was 4.8%; they yielded an average of \$0.129 in gold and \$1.11 in silver per ton.

REVIEW OF MINING

STRIKE AT THE PREMIER MINE IN BRITISH COLUMBIA

A strike involving 200 men has completely stopped operations at the Premier mine, situated in the Portland Canal district of British Columbia and controlled by the Guggenheims. According to dispatches, not only miners but the men employed in mill-construction and in erecting the new aerial tramway, have walked out. About the 4th or 5th of this month the company posted notices at the mine of a general cut in wages, ranging from 75c. to \$1.25 per day for various classes of labor, such cut to take effect the 16th of the month. This cut caused considerable discussion among the men, with the result that some 60 men, all of whom were handling ore, were discharged. The men apparently interpreted this as a manoeuvre to head off a strike; they quit in a body and deserted the mine, leaving no one except the office staff. The strikers have a number of grievances real or imagined. They find fault with the treatment of the 'old timers' at the hands of the mine manager; they complain of crowded bunk-houses and lack of recreation at the mine; and they resent the attitude of D. L. Pitt, the manager, as being generally "unreasonable" and antagonistic.

FINANCING FOREIGN TRADE

The War Finance Corporation has issued Circular No. 1 outlining, in a general way, the requirements of the Corporation in connection with applications for advances to American exporters and American banks, bankers, and trust companies for the purpose of assisting in the exportation of domestic products. The circular recites the law under which the Corporation is operating and sets forth the procedure that should be followed in making applications for advances. It also indicates the papers, documents, and other evidence required by the Corporation in connection with advances and includes suggested forms of application.

Copies may be obtained by exporters, bankers, and other interested parties upon application to the War Finance Corporation, Washington, D. C., or to the Federal Reserve Bank in the district in which they are situated.

COPPER-SELLING AGENCIES

The relative importance from the standpoint of output of the various groups of copper-mining companies is indicated in the following summary of the mines whose production is sold by different agencies. Guggenheim Brothers handle the marketing of more copper than any other interest in this country, representing as they do the so-called Hayden group of porphyries; also Braden, Chile, and Kennecott. Next on the list comes the United Metals Selling Co., which handles the marketing of copper for such important companies as Anaconda, Arizona Copper, Inspiration, Greene, New Cornelia, and North Butte. The Phelps Dodge Corporation ranks third in the list, representing its own properties as well as Arizona Commercial, Calumet & Arizona, Old Dominion, and United Verde Extension.

The companies marketing their copper through Guggenheim Brothers turned out approximately 500,000,000 lb.

last year, against 350,000,000 lb. by the United Metals Selling companies, and about 200,000,000 lb. by the Phelps Dodge companies. The American Metal Co. is an active selling interest and represents such companies as Cerro de Pasco, Granby, and International Nickel. W. P. Todd handles the marketing of East Butte and Davis Daly copper. Lewisohn & Sons handles the output of Miami and Tennessee Copper. The Calumet & Hecla sells its own production as well as that of its subsidiaries; also that of Hancock and Victoria. United Verde's output is sold through the United

British Columbia

States Smelting & Refining Co., and the American Metal Co., Copper Range, Mohawk, Wolverine, Mass Consolidated, Franklin, Magma, Mason Valley, Quincy, Shattuck-Arizona, and United States Smelting sell direct. American Smelting sells its own copper as well as that of Boleo, Gila, Howe Sound, and Ohio.

ARIZONA

Douglas.—The Calumet & Arizona company has closed its smelter. It will, however, keep the power-plant at the smelter in operation to supply power to the mines. All mining has been suspended and operating forces have been reduced from 2500 to between 40 and 50 men. These will be kept on the payroll to do underground development work. During the course of this work approximately 15,000 tons of ore per month will be hoisted. This will be shipped from the mines to the smelter and stored in the bins. These bins have a capacity of between 60,000 and 70,000 tons of ore.

Tombstone.—The mill of the National Metals Recovery Co. is working two shifts turning out good concentrate. The plant has been working without a hitch ever since it started and recoveries made have been gratifying. The mill has a capacity of 100 tons per 24 hours. It is an economical plant, working on the gravity system. It is in charge of J. W. Stockham.——Bert Holland and associates have been turning out concentrate for the past few weeks in the mill erected at the foot of Emerald dump and while the water question hampered work a little it is now running in good order.

CALIFORNIA

Altaville.—At the bottom of the 320-ft. shaft at the Victor gravel-mine a layer of blue clay, rich in gold, has been entered. Platinum also has been found in the black sand panned from the clay. Two assays of sand returned more than \$2000 per ton in platinum alone. A winze is being sunk to determine the depth of the deposit.

Angels Camp.—High-grade ore has been uncovered on the 500-ft. level of the Angels Camp Deep mine. John C. Benson states the vein contains free gold. It is believed to be the continuation of an important orebody opened some time ago on the 200-ft. level.

Coulterville.—The Virginia mine, formerly owned by the White Gulch Mining Co., has been acquired by a newly organized company known as the Virginia-Belmont Mining Co. The new owners have resumed development work. The mine is fully equipped and the 750-ft. point has been reached. Jack Wilson is superintendent.

Death Valley Junction.—The Pacific Coast Borax Co. is to resume shipments from the Death Valley mines about October 1, according to C. B. Zabriskie, general manager, who recently inspected the properties in Death Valley and also the newly found borax deposit in Clark county, Nevada. The company has completed the erection of a new dry-de-shaling plant, a patented process for removal of the shale remaining after the roasting. New Diesel engines and generators have been put in place and the capacity of the treatment plant has been enlarged 50% in expectation of increased business next year.

Grass Valley.—After working for six weeks to unwater the shaft and drifts of the Grass Valley Boundary mine at the west edge of Grass Valley, attempts at holding the water were abandoned after the vein had been thoroughly inspected. It was found that the heavy winter rains had caused an immense flow of water into the shaft, and it was virtually impossible to hold it with the present limited equipment. M. J. Brock, the promoter and manager of the property, is now getting estimates on the plant required.

Jackson.—Sinking has been started below the 4900-ft. level of the Argonaut mine. Forty stamps are crushing ore from the 4600-ft. level that is said to average \$15 per ton. Unwatering is still progressing at the Kennedy mine; production will start within 90 days, according to authentic reports.

Jamestown.—The old Rawhide mine is being re-opened. Thirty men have started to sink a new shaft on the property. The plan is to sink 1800 ft. Ore taken out as shaft-sinking progresses will be crushed in a Gibson mill. Arthur Knowles and associates are in charge of the work. The mine produced \$7,000,000 prior to 1915, when the known resources were exhausted. A new ore-shoot has recently been discovered.

Nashville.—O. A. Ingraham and C. A. Willhite have taken a lease of the Havilla mine from the Joshua Hendy estate. They say a ten-stamp mill will be erected at once and put in operation within 40 days.

Railroad Flat.—The old Ghost gold mine is being re-opened under the management of E. Saunders. This prop-

erty is one of the old mines of Railroad Flat district and holds a record for gold production.

Shasta.—F. A. Zimmerman and J. A. Anderson have cut into the vein in their Gold Dollar mine just north of town. By running a tunnel 100 ft. they struck the lode at a depth of 100 ft. The showing is good.

Sutter Creek.—Sinking has been resumed at the Hettie Green mine. Diamond-drilling has disclosed the existence of orebodies below the bottom level.

Improvements in the plant of the Central Eureka Mining Co. include the installation of a modern electric hoist to replace the present steam plant, and the erection of a steel head-frame, instead of the wooden structure now used.

The bins in the shaft are to be straightened and heavier rail will be laid. This will expedite the hoisting of ore and will permit more rapid lowering and raising of miners.

IDAHO

Coeur d'Alene.—The high price of silver and the increase in the price of lead are encouraging the mining industry in the district, and many of the smaller operators are preparing for development work during the summer. The Bunker Hill & Sullivan company has a large force at work in the mine. The main shaft has been sunk to the 1600-ft. level during the last five months and the output of the mine is approximately 1200 tons of ore per day. Twenty-five men are at work re-building the east mill, which was destroyed by fire last summer. The new mill will have a capacity of 500 tons daily. The Sweeny mill is operating at full capacity, handling lessees' ore and milling the old Sweeny tailing dump. The Bunker Hill smelter is handling 100 tons of ore and concentrate daily, and during the last week shipped 70,000 oz. of silver to the United States Mint at Denver.

In the upper workings of the Bunker Hill & Sullivan, the Reed Level Leasing Co. is employing 27 men; sufficient tonnage is in sight to continue work for several years.—The Stemwinder lease will resume work within a short time and ore will be milled by the Peoples concentrator. A number of lessees are at work in the old Last Chance and Sierra Nevada workings.—The North Bunker Hill Mining Co. has six men employed drifting on the 500-ft. level.

The Sterling Silver Co. in the Big Creek district has recently entered a vein of high-grade gray-copper ore and is planning further work.—The new mill of the Sunshine Mining Co. is well under way, lumber and equipment having arrived on the property in the last few days. Fifty men are employed on the Yankee Boy and Yankee Girl claims owned by the company.

Among the Pine Creek properties that have had favorable showings are the Highland-Surprise, situated a short distance from the Sidney; and the Constitution and Douglas on the east fork. Fred Ruch has been placed in charge of operations at the Sidney mine on Pine creek and will get out a shipment of high-grade ore from the surface showing. He also will start operations in the lower tunnel to cut the lode showing at the surface at a depth of over 400 feet.

The Peoples concentrator on Milo creek above Wardner is being overhauled and will commence operation within the next month. The entire mill is being repaired, a new set of rolls and a Dorr thickener are being installed. The concentrator has a capacity of approximately 100 tons of ore daily.

Ore shipments are going ahead from the Western Union mine. A car of ore was shipped recently and another is ready for shipment. The ore averages 44 oz. silver and better than 50% lead. Good progress has been made on the tunnel, which is in 200 feet.

Some conception of the importance of leasing operations in the Coeur d'Alene is obtained from the announcement that the Bunker Hill & Sullivan company last year received

\$69,226 from royalties paid by miners who lease from that company alone.

Pocatello.—The Idaho Leasing Co., operating the old Black Bear property at Mace, now owned by the Federal Mining Co., shipped its second car of ore recently. There are still two cars of ore in the bins. The ore is being shipped to the American Smelting & Refining Co.'s smelter at East Helena. The tram that has been under construction for several weeks has been completed and is in good running order. The concentrating plant will be slightly changed in order to add to the efficiency.

MICHIGAN

Houghton.—Settlement of the reparations matter will, local mining men believe, work to bring about an improvement in the metal market. They give several reasons for this belief. Trade with Germany and the allied countries will be placed almost immediately on a better basis, and

factorily. Efforts are now centred on drifting south from the 942-ft. level of the New Baltic shaft toward the New Arcadian shaft with which connection will be made at the 900-ft. level. Drifting north has been stopped temporarily. The south drift is in 120 ft. It is in the lode and the vein 'rock' is of encouraging character, samples showing barrel copper well distributed.

Mayflower is drilling southward from the east cross-cut at the 1700-ft. level in a section of what appears to be the Mayflower vein. Work in the west cross-cut has been temporarily abandoned. Operations there were successful in enabling the management to obtain accurate data as to the extent of faulted ground in that direction. In the east, the drills have passed through vein matter well impregnated with fine copper. The showing there is encouraging for a distance of fully 200 ft. Mayflower is nearer to the sandstone than other mines and has had fewer data to work on than any of the other properties. It has been discovered

Panoramic View of Oatman District in Arizona

copper, in their estimation, will be one of the first commodities to 'come back' in this revival. Germany, it is pointed out, is denuded of copper and must come into the market in greater volume than in the last few weeks. During the War, Germany not only used up all of its surplus stocks but stripped the country, confiscating roofs, bells, copper utensils, and even door-knobs to salvage the copper for munitions purposes. This metal must be replaced to a large extent, and Germany, too, will strive for maximum production in order to meet the allied demands. All this will require, it is believed, large new stocks of copper. Before the War, Calumet & Hecla disposed of about 70% of its metal to Germany. Since the War, Calumet & Hecla has had to rely entirely, with the exception of the last few weeks, on the domestic market. With little or no demand for the metal, however, copper has been piling up. The recent shipment of 200,000 lb. of metal to France by Calumet & Hecla may indicate the early return of France to the market. France has been relying largely on scrap copper salvaged from the battle-fields, but it is believed this stock has been largely exhausted.

Wolverine has completed the work of taking out the pillars on the 38th level of No. 4 shaft and is now at work on the 37th-level pillars. The 'rock' continues to average around 15 lb. of copper per ton. In conjunction with this work, drifts are being widened out and the backs of stopes removed in the upper levels. Wolverine is employing close selection in its mining. Wolverine will make no attempt to explore other lodes on its property until there is a marked improvement in metal-market conditions.

Development work in New Arcadian is proceeding satis-

factorily. Efforts are now centred on drifting south from the 942-ft. level of the New Baltic shaft toward the New Arcadian shaft with which connection will be made at the 900-ft. level. Drifting north has been stopped temporarily. The south drift is in 120 ft. It is in the lode and the vein 'rock' is of encouraging character, samples showing barrel copper well distributed.

Calumet & Hecla has installed a compressor, electrically operated, in the 81st-level cross-cut, east of the Red Jacket shaft, to supply air for the drills on the Kearsarge amygdaloid lode. This will result in a saving, for it will make it possible to suspend the operation of the big steam-compressor on the surface. There is no change in the Kearsarge lode developments, and stretches of good ground alternate with comparatively barren strips.

Seneca's third level, north, which is breasted 1500 ft. from the shaft, continues to open good ground, while the fourth-level stope, also in the north, is yielding the same high quality of rock that was noted from the beginning of this phase of the program. The fifth and sixth, north, also are in fair ground so that all openings are encouraging. About seventy men are on Seneca's payroll.

MISSOURI

Joplin.—The Eagle-Picher Lead Co. has resumed production on a normal scale. Recently 450 employees have been called back to work in the various departments of the enterprise.

MONTANA

Butte.—Ore mined by the Davis-Daly company during the first quarter of 1920 averaged 6.21% copper and 5.49 oz. silver. The number of men in the mining force has been reduced to about 200. Since the fan was started in the new ventilation shaft the average temperature on the 2700-ft. level has been lowered more than 20°. Surface improvements have been completed and the mine is now in a condition to operate to capacity, with the maximum of efficiency. Developments on the 2400 and 2700-ft. levels are gratifying. The Hibernia mine has continued to be of great value in offsetting the losses in the Colorado operations, the production of silver ore being the highest in recent years. The production by lessees at the Hibernia mine amounted to 18,147 tons, producing 361,059 oz. of silver, the average assay being 20.56 oz. per ton.

Great Falls.—One unit of the Anaconda company's smelter and one of the rolling mills at the plant have been placed in operation. Silver and lead ores are being treated, giving employment to 100 men. Other parts of the plant have been closed down, operation of the copper furnace-refineries having been suspended last week.

Marysville.—The following returns are reported from the mines of the Barnes-King Development Co. for April 1921. The Shannon mine shipped 3321 tons of ore, averaging \$8.44 per ton; the net bullion produced therefrom amounts to \$27,945. The North Moccasin lessees mined 1320 tons of ore, with an average assay value of \$6.15 per ton, on which the company will receive \$769 royalty.

NEVADA

Candelaria.—Construction of the first unit of a cyanide plant for the Candelaria Silver Mines Co. will begin at once, according to a statement made by C. D. Kaeding, consulting engineer and manager for the company. Crushing-machinery with a capacity of 400 tons daily will be installed and the first unit of the cyanide plant will treat 150 tons daily and will be completed by the time the electric transmission line from Hawthorne reaches the camp, probably late in August. The control of the enterprise is held by the International Nickel Co., one of the largest operating concerns in America, which operates the Dome Mines, Ltd., at Porcupine, and other large mines in Canada.

Ely.—The Nevada Consolidated Copper Co. milled 381,092 tons of ore, averaging 1.49% copper, during the first quarter of 1921. There was shipped direct to the smelter from the Ruth mine 5459 tons of ore, averaging 10.92% copper. Of the total tonnage treated, 66% came from steam-shovel workings and 34% from underground workings.

Lewis.—An 18-in. seam of \$4000 silver ore has been opened on the 150-ft. level of the Betty O'Neal at a point 450 ft. south of the shaft. The silver is in the comparatively rare forms of stephanite and polybasite, sulphantimonites. The vein where the find was made is 5 ft. wide and the ore aside from the rich seam assays \$30. There is 350 ft. of unexplored ground above this ore, which is in the Estella vein, and a tunnel is now being driven to cut this vein 150 ft. below where the find was made. In the early days the Betty O'Neal was a good producer of rich ore and it is now being re-opened. An air-compressor was hauled to the mine recently from Battle Mountain, for use in driving a 2000-ft. tunnel that will cut the two veins at a depth of 1300 ft. It is estimated that it will require eight months to drive this tunnel to a connection with the 300-ft. level of the Betty O'Neal shaft, on the 150-ft. level of which the \$4000 ore was found. When this tunnel has been completed a 125-ton unit of a 500-ton concentration and cyanidation plant will be built at the portal. Money to bring the present plans to completion has been supplied by the George W. Sias Co. of Boston. The mine manager is Noble H. Getchell, son of L. W. Getchell, who formerly owned the property.

Pioche.—Official confirmation of the reported new finds of rich ore on the Nevada Silver Horn and Silver Dale properties at Silverhorn has been made. At Rattlesnake Point, about 300 ft. east of the mineral monument on the Nevada Silver Horn, J. Nelson Nevius has opened a body of ore, samples of which assay as high as \$100 per ton in silver. This has already been proved for a width of 10 ft. and a length of 40 ft. Good progress is being made in carrying out plans for prospecting the vein for 1200 ft. in length by means of three adits and a drift from the bottom of the Whipple shaft, there being a difference in elevation of about 70 ft. between each of these.

R. M. Geppert has completed a two months geological study and sampling of the Silver Dale and has left for his home in Minneapolis. Mr. Geppert uncovered what apparently is the source of rich float found some time ago on the south end of the Silver Dale. Assays of this float were rich; the ore in place is not so rich, but is promising.

Work on the Silver Peer is confined to the 120-ft. level where the orebody is reported to average \$10 per ton for a width of 40 ft. Word has been received that Walter Geddes has sold a big interest in the Peer to Tex Rickard. Business houses of all kinds are being opened rapidly and Silverhorn is assuming the appearance of permanency. The rush into the district continues and the population is increasing rapidly.

Silver Peak.—An 8-ft. width of \$80 silver ore has been found in a 70-ft. shaft in a new district called Cow Camp, 12 miles south of Silver Peak. The work is being financed by a man named Sanger of Bishop, California.

Tonopah.—The Tonopah Extension has resumed work with 50 men and there are indications that the wage-cutting companies will continue to import miners until full crews have been obtained. Buildings are being prepared in which these men will be housed. There has been no trouble of any kind except that the rails were greased for a train reported to be taking in strike-breakers. Men returning to work are permitted to do so without interference. It is estimated that 25 to 30% of the number of men employed before the strike are now at work. Communications, one faction to the other, have only served to make certain the early indicated attitude of the operators that they would not make concessions. The quickness with which the wage-cut was announced by the operators is said to have been in retaliation for the suddenness with which the workers broke their agreement some months ago, when they refused to work under reduced wages previously agreed upon.

Virginia City.—At a depth of 170 ft. the new inclined shaft of the Comstock Silver Mining Co. is in ore assaying \$15 per ton across the full width. The shaft is following the dip of the vein. The ore contains gold and silver, showing coarse particles of gold in pinnings, and is typical of the deposits of the Silver City part of the district, where the precious metals are found in association with manganese. —Development work is to start at once on the Overland property, adjoining the main group and which was purchased lately by F. M. Manson for the Comstock Silver Co. This property is equipped with a 10-stamp mill and complete mining plant and buildings and has produced over \$500,000 from its 550-ft. shaft on the Succor vein.

NEW MEXICO

Hurley.—During the first quarter of 1921, the Chino Copper Co. treated 345,660 tons of ore, a daily average of 3840 tons, or 611 tons less per day than for the preceding quarter. The ore averaged 1.69% copper, and the recovery per ton was 25.78 lb. There was produced 20,731 dry tons of concentrate, averaging 21.50% copper, resulting in a gross production of 8,913,405 lb., as compared with 10,457,661 lb. for the last quarter of 1920. The net cost per pound

of copper produced was 14.56c., as compared with 13.93c. the previous quarter. Payment for precious metals and miscellaneous income were equivalent to 0.81c. per pound. The operating loss was \$122,949, while miscellaneous income was \$69,812, leaving a net operating loss of \$53,136. Copper was carried at an average price of 13.13c. in arriving at the above figure. At the present time, Chino has about 300 men on the payroll. Over half of this number are Mexican laborers, who are in more or less destitute circumstances and to whom the company is giving employment at \$2 per day.

OREGON

Gold Hill—The War Eagle Mining Co., producer of mercury, has closed down its Scott furnace, but is going ahead with development work in the mine. The closing down of

G. D. O'Connor, manager. This company's holdings are situated to the west of the Great Salt Lake, near the Western Pacific railway. In addition to the drifting, two shafts are to be sunk. A five-inch streak of high-grade ore is being followed, assays of which give returns from 30 to 200 oz. silver. A shipment is being prepared for market.

Eureka—The raise started from the face of the Tintic drain-tunnel to the surface, a distance of over 600 ft., has been completed. This will be of assistance in affording better ventilation for the property. The Knight interests are in control of the property; the tunnel is projected for the purpose of draining the south end of the Tintic district.

Shipments from the Tintic district for the week ending May 14 totaled 129 cars, a decrease of 5 from the previous week. The Tintic Standard shipped 43 cars; Chief Con-

The Granite Mountain Shaft of the North Butte Mining Co.

the furnace is not due to the low price of mercury, but to the refractory nature of the ores in the lower levels, which contain arsenic and other refractory minerals. Metallurgical tests are to be made.

The old Bertha gold-quartz mine on Foothills creek has been acquired by Kellogg & Donagan of Gold Hill, who are re-opening the old workings.—Chester Kubli, of Jacksonville, a part owner in the old Kubli gold-quartz mine five miles south of Gold Hill, is re-opening the mine for operations.—Carter & Rawles, who recently acquired the Red Oak gold-quartz mine adjoining the Kubli, are re-opening and developing.

Jacksonville—The Blue Ledge Mining Co. that has been mining copper ore without interruption since the War has closed down. The proposed construction of the \$50,000 electric power-plant has been indefinitely postponed.

UTAH

Arnold—Drifting has been started from the north shaft at the Pennu Copper Mining Co.'s property, according to

solidated, 35; Iron King, 15; Dragon, 12; Iron Blossom, 8; Eagle & Blue Bell, 5; Victoria, 3; Gemini, 2; Colorado, 2; Eureka Bullion, 1; Mammoth, 1; Bowers, 1; Eureka Hill, 1.

The shaft at the Zuma property will be extended from the 500-ft. level to the 1200-ft. level, according to A. C. Nebeker, superintendent. A small amount of work performed by means of winzes below the 500-ft. level has proved the existence of ore as deep as the 900-ft. level, and a recent shipment was taken from this development work.

Milford—About one carload of ore per week is now being shipped from the Gold Crown property near here. The ore averages \$2 in gold, 22 oz. in silver, 0.9% copper, and 18% lead, with an excess of iron. When this property was first opened some years ago, it attracted attention owing to the fact that ore was found close to the surface. Under the management of James Kirk, development operations resulted in opening three feet of ore on the 250-ft. level, shipments from which netted \$46 per ton. At a depth of 400 ft. the ore has been proved for a width of three feet and a length of about 55 ft. G. L. Williams is now in charge.

Park City.—Ore shipments for the week ending May 14 totaled 1545 tons, as against 1112 tons for the week preceding. The Silver King Coalition shipped 734 tons; the Judge allied companies, 636, and the Ontario, 174 tons.

Salt Lake City.—Outstanding features of the Utah Copper Co.'s report for the first quarter of the year 1921 are the improvement in the grade of ore treated, an increase in the percentage of recovery, and a net deficit of \$1,714,317. The net loss from copper production was \$53,616. Miscellaneous income, including payment for precious metals, made the total income for the quarter \$215,715. Loss on government bonds sold being \$305,543, the total net loss for the quarter amounted to \$89,827. Disbursement to stockholders of \$1 per share or a total of \$1,624,490 made the net deficit for the quarter, \$1,714,317. The total quantity of ore milled during the quarter was 1,202,700 dry tons, being 144,300 tons less than the preceding quarter. The average grade of the ore was 1.16% copper and the average extraction was 83.87%, as compared with 1.11% copper and 79.89%, respectively, for the previous quarter. The average cost per net pound of copper produced from concentrates and leaching-plant precipitates was 13.18c., without credit for gold and silver or miscellaneous income. This cost includes all fixed and general charges, but excludes Federal taxes and depreciation. After deducting 1.19c. for gold and silver credits and miscellaneous income the net cost was 11.99c. per pound.

Tooele.—The new mill of the Utah Consolidated Mining Co., near the terminus of the company's tramway from the mines at Bingham, is nearing completion. The results of milling-tests made last year on copper ores showed that a considerable saving could be made by concentration. Seven tons was put into one and a product made on which the smelter has given a favorable contract. Plans were completed, and in July 1920 construction work started on a 1000-ton concentrating plant. The mills situated within a few hundred feet of the International smelter and alongside the company's present aerial tramway, which extends from the mine four miles distant to the smelter. The work on the building and installation of machinery has progressed satisfactorily, although the work has not been rushed, owing to the low price of copper.

There is in sight in the mine 815,000 tons of copper ore, averaging 1.96% copper, 0.57 oz. silver, and 0.04 oz. gold.

WASHINGTON

Keller.—Richard Marsh, of Spokane, has taken a contract to build and superintend a cyanide plant which the Keller Copper Co. will construct at its property, 12 miles north of here. March will start construction at once. The cyanide plant will handle 20 tons of ore per day; the company already has a mill with a daily capacity of 40 tons.

BRITISH COLUMBIA

Ashcroft.—The Hellsgate Mining Co. has been incorporated here for the purpose of developing the dry-placer deposit discovered recently near Spence's Bridge.

Prince Rupert.—There is anxiety with regard to the reopening of the Dolly Varden mine. The average run of the ore is less than 40 oz. of silver per ton, and, unless a concentrating plant is built it seems possible that the mine will not be worked until there is an improvement in the price of silver.—There is no mining of any description on the Kitsault river and only a few men are employed on the Illiance river. The present indications point to a dull season.

Slocan.—At the Ottawa mine on Springer creek, A. L. McPhee and associates have resumed work on the new concentrator; it will be handling ore within 60 days. As soon as the mill is working the owners will resume development underground.

Trail.—In the first four months of this year the Trail smelter has received for treatment 149,677 tons of ore and concentrates. This is 50,936 tons, or 50%, more than in the first four months of last year. Almost the entire tonnage is now coming from the mines owned by the Consolidated Mining & Smelting Co. of Canada, which owns the smelter. Total receipts for the year, to date, are divided as follows: Company's mines, 147,579; Gold Hill, Taghum, 33; Millie Mack, Burton, 12; Bell, Beaverdell, 16; Horn Silver, Chopaka, 260; Sally, Beaverdell, 33; Sutherland & Thompson, Beaverdell, 7; Black Prince, Slocan City, 57; Blue Bell, Riondel, 1114; Gem, Sandon, 11; L. T., Slocan City, 11; Nip and Tuck, Sandon, 6; No. 1 Ainsworth (lessees), 112; Ruth, Sandon, 21; North Star, Kimberley, 111; Paradise, Lake Windermere, 213.

Vancouver.—The Homestake Mining & Development Co. has been organized to take over and operate the Homestake group in the Alice Arm district. The capital of the company is \$500,000 and the consideration for the claims is \$115,000.—The Calcining Process Co. has been formed to manufacture natural and portland cement, and to calcine limestone, gypsum, and magnesite by a new method.

Victoria.—The Western Abrasive Paper Co., of this city, has leased a garnet mine at Wrangel, Alaska, from the Alaska Mining & Manufacturing Co., of Minneapolis. R. J. Frizell, one of the directors of the abrasive company, has left for Wrangle to superintend mining operations.

BURMA

Rangoon.—The New Coal Mining Co., at Loia, which recently commenced the mining of coal, has been taken over by the new Indo-Burma Oil Fields. It is reported that copper has been found in the southern Shan States, and there seems to be no doubt but that large deposits will be uncovered. The New Consolidated Gold Fields had been granted permission to prospect for ores in the district east of Lashio in north-eastern Burma.

JAPAN

Tokyo.—According to a consular report the copper market in Japan continues inactive, and there is no immediate prospect of a revival. Upward of 32,000 tons of copper is now accumulated in Tokyo, Osaka, Kobe, and other principal cities, and the monthly output by various copper-mining companies in Japan amounts to 5000 tons despite the curtailment of working hours since last summer. The Government has been asked to render aid to copper refiners, but under existing conditions it is impossible for the authorities to grant the request. Apprehension is therefore felt that quotations in Japan will show a further decline in the near future.

The exports of Japanese copper declined from 160,429,333 lb. in 1917 to 71,253,333 lb. in 1918, 43,208,000 lb. in 1919, and 23,300,000 lb. in 1920. The refining companies have been endeavoring to export stocks to India and the South Pacific countries, where the metal has been consumed in large quantities in recent years, but there is no immediate prospect of the output being shipped to these countries because of the universal economic depression. During January 3000 tons was shipped to China, while in February the total shipment to that country was only 300 tons. In view of the fact that the price of copper in China is still on the decline, the trade with that country is regarded as being hopeless during the next few months at least. A proposal is therefore advanced to further reduce the output on the part of six large copper-refining companies in order to save the situation and at the same time to resort to dumping on the European market.

MEXICO

Guanacavi (Durango).—Considerable activity continues here. Development work is being done on a number of re-

cently denounced properties and some new applications have been filed. Guillermo Donatlan has taken up a small group to be titled under the name of La Aurora, situated on the Tres Varones mesa adjoining the Doris, Dos Estrellas, and El Aguila mines.—It is still rumored here that Hilario Lozoya has interested American capital for the construction of a smelter here.

Monterrey.—One of the interesting phases of the present mining situation in Mexico is the widespread prospecting that is going on, particularly in mountain localities that are far removed, in some instances, from any actual mining development. There has been a rush of American mining prospectors to Mexico recently, and for the first time in many years the old-time 'grubstake' seeker for gold and silver is traveling through the mountains with his pack-mule. Recently claims were filed on upon the San Rafael ranch, in a remote part of the State of Durango by Andres Arrieta of Topia, a well-known mining man who plans to start development work upon the property soon.

Regular shipments of silver ore will be started from the Guadalupe group of mines, in the Topia district, by Walter C. Minsch and Martiniano Aguirre. Development work is now in progress upon the property, it is stated.

The Mexican National Resources Co. which was recently formed in San Antonio, Texas, has taken over 40 mines in the States of Chihuahua, Sinaloa, Guerrero, Zacatecas, and Oaxaca, which passed from the hands of their owners by forfeiture for non-payment of taxes to the Government. It is stated that these properties are valued at several million dollars. Among the men who are interested in the new company are: W. W. Collier, president of the State National Bank of San Antonio; Harry Landa, manufacturer; Dr. F. J. Combe, president of the Southern Life Insurance Co.; J. E. Jarrett, and William Tracey Page. Dr. George C. Hinton of New York is also interested.

Saltillo (Coahuila).—A group of four claims to be titled under the name of Santa Teresa has been taken up by Felipe Zertuche. The property is situated in the Ferniza district near Saltillo and embraces a well-defined vein of silver-lead ore.—Tobias E. Guzman has filed on the Iturbide group of four mining claims situated in the municipality of Viesca. The property is situated near El Cobre mine in the famous Jimulco copper district.

Torreon (Coahuila).—The Torreon smelter, which blew in the first of this month, continues to operate and is receiving a few small shipments of ore from the nearby districts, although no new contracts are being made. Due to an improved condition of railroad traffic a sufficient supply of fuel is procurable.

Recent reports from Chihuahua are to the effect that some of the mines of Velardeña belonging to the American Smelting & Refining Co. will be operated and the ores shipped to the Chihuahua plant. The smelter is operating.

ONTARIO

Cobalt.—During April the Nipissing mine produced \$142,610. A new shaft-house is being erected at shaft 73 where a fire destroyed the former structure.—High-grade ore has been found at a depth of 360 ft. in the Keeley Silver mine. It is too soon to estimate the importance of the find. Arrangements are being made to resume operation on the Cobalt properties of the Mining Corporation of Canada. The mill has been enlarged so as to treat 300 tons of ore daily as compared with a former rate of 200 tons.

The Oxford-Cobalt property and the Victory Silver Mines have both resumed work. The plant on the Coniagas mine is treating 600 tons daily. This is made up of 300 to 350 tons of ore, 100 to 150 tons of slime, and 100 to 150 tons of sand tailing. The slime is cyanided and the sand is re-ground and treated by oil-flotation.

RUMANIA

The total production of crude-oil in Rumania for March 1921 was approximately 633,591 bbl., against 575,743 in February. Of the total, Steaua Roman produced 122,370, Astra Romana (Royal Dutch Shell) 125,755, and Romana Americana (Standard Oil) 148,715 barrels.

SOUTH AFRICA

Cape Town.—Reports to the effect that important discoveries of platinum have been made recently in the Cala district of South Africa are arousing interest. Platinum ores are not unknown in the Union. They have been traced for several hundred miles along the margin of the Bushveld granite area in the Transvaal, but this locality has not so far been exploited, though samples have been assayed from time to time. Discoveries have also been made in the north Lydenburg district, but unfortunately this part of the coun-

Northern Mexico

try lies over fifty miles from a railway and is almost inaccessible. A reconnaissance has been made, however, by the Railway Department, and in time this district will be opened and the deposits brought within reach of a market. It is probable that richer ore may also exist in other portions of these deposits.

YUKON

Dawson.—Ice in the Yukon river commenced to break up on May 12, accompanied by the usual blowing of whistles and ringing of bells that annually marks the occasion. The Dominion government has extended the privilege to the 'Alaska' and the 'Yukon', United States ships now at White Horse, to carry silver ore awaiting transportation at Mayo Landing.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. A. Poirier, of New York, is at Porcupine.

W. H. Landers is at Charleston, West Virginia.

Hugh Rose is on his way from Mexico to London.

Charles W. Goodale is at Marlboro, Massachusetts.

G. A. Collins, of Vancouver, was recently in New York.

George A. Camphuis, of Oro Blanco, Arizona, is in London.

W. R. Ingalls is director of the Bureau of Metal Statistics.

Karl F. Klein has moved from Antofagasta, Chile, to New York.

Gerald B. Street, of Wilmington, was in San Francisco recently.

Henry Hanson, of San Francisco, is at Keeler, California, for the summer.

C. L. Ball is general manager for the Huanchaco company, in Bolivia.

A. C. Terrill is professor of mining at the Pei Yang University, Tientsin.

McHenry Mosier has moved from Avalon, California, to Douglas, Arizona.

G. C. Ripley has moved from Great Falls, Montana, to Denver, Colorado.

E. J. Safford has moved from Matehuala, Mexico, to Fresno, California.

Gelasio Caetani has been elected a member of the Italian Chamber of Deputies.

William Wallace Mein, of New York, is at Lake Tahoe, California, for the summer.

John F. Newsom is expected in San Francisco on his return from the Malay States.

W. H. Leonard, of the Denver Rock Drill company, was in San Francisco this week.

F. G. Janney, general superintendent of mills for the Utah Copper Co. at Garfield, is at Chicago.

A. Harms, assayer for the A. S. & R. Co., at Hayden, Arizona, has gone to Rock Island, Illinois.

Alejandro LaCasa, a mining engineer from Madrid, Spain, is visiting the mining districts of Utah.

Frederick H. Minard has transferred his office to the new Liggett Bldg., 47 East 42nd St., New York.

Robert J. Grant has been recommended for the appointment of superintendent of the Denver mint.

W. E. Harrison, who recently resigned as State Inspector of Metal Mines in Utah, is at Pioche, Nevada.

Hallet R. Robbins was in San Francisco on his return from New Mexico. He has gone to New York.

Henry I. Altshuler has gone to Mexico to work with the San Luis Mining Co., at San Dimas, in Durango.

Bradley Stoughton has resigned as Secretary of the American Institute of Mining and Metallurgical Engineers.

Frederick G. Clapp and the Associated Petroleum Engineers have removed their office to 30 Church St., New York.

N. Takahata, mining engineer associated with Furukawa & Co. of Tokyo, has been visiting mining districts in Utah.

E. V. Daveler, mill superintendent for the Butte & Superior Mining Co. at Butte, was at Salt Lake City and Denver recently.

C. B. Neiswender, who was until recently on the staff of

the Inspiration Copper Co., is now in consulting practice at Los Angeles.

J. D. Shilling, general superintendent of the Utah Copper mine at Bingham, is spending a vacation on his ranch in southern California.

W. F. Garland has been elected a member of the board of directors of the Mysore Gold Mining Co. after having served as secretary for twenty years.

R. L. Agassiz, president of the Calumet & Hecla, has been elected president of the Copper Export Association, succeeding John D. Ryan, who declined re-election.

Archie McDonald, formerly connected with the Snowstorm Mining Co., of Idaho, has been appointed manager for the Sterling Mining & Milling Co. at Wallace, Idaho.

C. V. Corless, manager for the Mond Nickel Co., and president of the Canadian Institute of Mining and Metallurgy, recently received the degree of LL.D. at Queens University.

E. C. Lane, of the San Francisco laboratory of the Bureau of Mines, is on a visit to the Bureau Stations at Bartlesville and Pittsburgh. He will visit Washington before returning to San Francisco.

T. Kawaseki, Professor of Mining in the Port Arthur Engineering College, South Manchuria, passed through San Francisco on his way to study mining engineering at the University of Illinois, at Urbana.

Frank R. Wicks has returned from New York to Los Angeles after an absence of four months. He expects to leave again next week for Tiger, Colorado, and will probably remain there some months. He is now general superintendent for the Royal Tiger Mines Company.

Obituary

Arthur L. Pearse died at New York on May 14.

David Goodale, of the firm of Atkins, Kroll & Co., died at Berkeley on May 23. He was born in San Francisco 43 years ago and graduated from the State University in 1900. His untimely passing is deeply regretted by a wide circle of friends.

William Sylvester McCornick, a prominent figure in Western financial, industrial, and mining circles for the past fifty years, died at his home in Salt Lake City on May 18, at the age of 84. He underwent the amputation of his right leg on May 3, and for a time it appeared that he would recover, but the shock of the operation and subsequent complications proved too much for his strength. He was born near Picton, Ontario, on September 14, 1837, and, until he was 21, worked on his father's farm, obtaining an education in the village school. In 1860 he went to California and settled in Marysville, where he engaged in farming for two years. He then went to Comstock, Nevada, and entered the contracting and teaming business. Later he became interested in mining in Nevada. In May 1873 he came to Utah and started a private bank. His money and his executive ability proved the controlling factors in the development of mining properties that became prominent dividend-payers. At the time of his death he was a director and treasurer of the Silver King Coalition Mines Co., and also a director of the American Smelting & Refining Co. He was interested in the Daly West mine at Park City, and in the Centennial-Eureka and Grand Central properties at Eureka, Utah. He married Hannah Keogh, of Belleville, Ontario, on June 16, 1867, and to them were born ten children. He was active in business up to the time of his death. In his death, Utah loses one of its foremost citizens, and Salt Lake City business circles one of its ablest, most honored, and highly esteemed members.

THE METAL MARKET

METAL PRICES

San Francisco, May 24

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	7.50
Copper, electrolytic, cents per pound.....	13.00—13.50
Lead, pig, cents per pound.....	5.25—6.25
Platinum, pure, per ounce.....	\$75
Platinum, 10% iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$50
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	9.00—9.50

EASTERN METAL MARKET

(By wire from New York)

May 23.—Copper is more active and higher. Lead is quiet but firm. Zinc is inactive but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

SECRETARY MELLON'S TAX PROGRAM

A correspondent in 'The Annalist' says: The letter sent to the Senate Finance Committee and House Ways and Means Committee by Secretary Mellon gives a fairly comprehensive idea of the program which the majority of the administration leaders hope to carry out in revising the revenue law. Mr. Mellon would reduce the upper brackets of the surtaxes on personal income so that in 1921 the combined normal and surtax shall not exceed 40%, and in the years thereafter shall not exceed about 33%. This means that the combined tax for 1921 shall include the normal tax of 8% and the surtax of 32%, the surtax now paid on that part of the income, which is above \$66,000, and does not exceed \$68,000. In other words, persons having incomes of more than \$68,000 would pay what amounted to a tax of 40% on their total income. Under the present law the surtax, in addition to the normal tax, rises gradually to a peak of 65%, which is collectable on that part of the income designated as "1,000,000 or more". The actual peak in the present law, taking into consideration the normal tax of 8% as well as the surtax of 65%, is 73%. In the years after 1921, under the Mellon plan, the normal 8% tax and the present surtax rates up to 25% would be collected.

It is pretty generally admitted here among students of the tax and revenue problem that the upper brackets of the surtaxes—those above 32%—are relatively unproductive. Mr. Mellon's statement that they would yield not more than \$100,000,000 per year came as something of a surprise to many, but that is what the statistics show. It is probable that Mr. Mellon's statement that a reduction of the surtax rate would bring about a turnover of securities which would yield a larger amount of revenue to the Government will stand the acid test. Such a revision at the same time may give comfort to the possessors of great fortunes, but from the practical viewpoint of the amount of revenue collected the Government might be better off.

There would seem to be little or no doubt that both branches of Congress will agree to wiping out the excess-profits taxes. In its place Mr. Mellon suggests a flat additional tax on corporate incomes which would avoid determination of invested capital. He is convinced that a tax of this character at the rate of 5%, combined with the repeal of the \$2000 exemption applicable to corporations, would yield about \$400,000,000. The outlook is that some such plan will be brought about.

There is bound to be a fight, however, for the repeal of the tax on transportation, which Mr. Mellon says must be retained because of the large yield to the Government. Another fight is almost certain to centre on propositions which have been made for a more general repeal of taxes which hit the pocketbook of the masses, such as the tax on theatre admissions and sporting goods, the retention of which Mr. Mellon holds to be essential.

While it seems to be the opinion of Mr. Mellon that the national budget cannot be kept under \$4,000,000,000 for 1921 or 1922 the general tenor of his recommendations have brought a reassuring note into the situation. It is noticed that he has made no provision for the payment of soldiers' bonuses in his recommendations.

MONEY AND EXCHANGE

Foreign quotations on May 24 are as follows:

Sterling, dollars:	Cable	3.96%
	Demand	3.97 1/2
Francs, cents:	Cable	8.62
	Demand	8.64
Lire, cents:	Demand	5.50
Marks, cents:	Demand	1.70

Eastern Metal Market

New York, May 18.

There has been no great change in any of the markets. Buying is not heavy and prices of one or two metals have developed some softness.

Foreign buying of copper continues with a slight improvement in domestic demand. Prices are higher.

Buying of tin is moderate and the market is firm.

Demand for lead has eased off and values are lower.

No improvement has developed in the zinc market which continues lifeless and softer.

Antimony is unchanged and inactive.

IRON AND STEEL

The prospect of quietness in the summer months is more influential in the steel market, says 'The Iron Age'. Producers now are quite unanimous in seeing only a few weeks ahead a slackening in the activities of automobile works which have been the chief basis of hope recently. Steel works are running at 30 to 35% of capacity, on the average, and some important companies put the amount of new business at about one-third normal bookings. The Steel Corporation, which had a poor average of new business in March and April, particularly in March, when its price reductions were impending, has found its orders since May 1 running nearly 30% more than the average for the two preceding months. This is better than most independent companies are doing and is due in part to current export business.

The railroads are even less disposed than they were earlier in the year to receive deliveries on orders placed with steel mills. Five important Western lines have laid no rails this year, despite the fact that a good many of their 1921 rails have been delivered. One line has had 60,000 tons delivered; this it has put in storage.

COPPER

An interesting birds-eye view of the copper market is about as follows, in the opinion of one large seller: Present rate of production is down to about 40,000,000 lb. per month while deliveries into consumption, foreign and domestic, will probably average 100,000,000 lb. per month this year. This should in the long run make the copper position strong. As European buying improves, and it should from now on, domestic buying will pick up.

Prices are advancing and the market tone is better and firmer. Electrolytic copper for May-June delivery can probably not be bought for less than 13c., delivered. This is the firm price of all leading producers and others seem to be up to this level or higher. Sales to foreign buyers predominate though domestic demand, or at least inquiries, are better. It is figured that sales for foreign consumption have totaled 10,000,000 lb. in the last two or three weeks. Another seller states that demand appears to have been in waves recently, March having been mostly foreign; April, domestic; and May now foreign again. We quote the electrolytic market at 13c., delivered, or 12.75c., New York, for May-June delivery. Lake copper is also higher at 13c., New York, or 13.25c., delivered, for the same positions.

An interesting statement is that German producers of copper products can sell their products in France cheaper than can French producers, after paying transportation and import charges, and the same price for American copper that French buyers do.

TIN

The market while quiet is strong, particularly abroad. There has been very little buying by consumers, but there has been the usual moderate volume of purchasing by deal-

ers. Even London dealers have been in this market, due to higher prices prevailing there; this demand has been even larger than the combined consumers' and dealers' domestic buying. The business done has involved May-June-July arrivals largely; the largest volume was on last Thursday when total sales amounted to about 850 tons. On other days, the offerings were less plentiful. Prices in London are higher than a week ago by £7 to £8 per ton, spot standard yesterday having been quoted at £181, future standard at £182 15s., and spot Straits at £187. Spot Straits tin at New York has hovered around 32 to 33c., the quotation yesterday having been 33.25c., New York. Arrivals thus far this month have amounted to 605 tons with a total of 2150 tons reported afloat.

LEAD

No developments of any marked importance have been reported. The market is quiet and prices are easier. Demand has fallen off and inquiries are not so numerous. The leading interest is evidently taking some of the business at its regular quotation of 5c., New York and St. Louis, and the remainder is going to independents at around 4.95c., St. Louis, or 5.12½c., New York, which we quote as the market. Part at least of the 10,000 tons of Spanish and foreign lead that has reached this market has been held in storage, it is reported.

ZINC

Still lifeless and without feature is the report on this market. Prime Western for early delivery is obtainable as low as 4.85c., St. Louis, or 5.35c., New York, which we quote as the market. Many producers will not sell under 5c., St. Louis, but one or two will part with a carload or so at the lower prices, demand being confined to small amounts. Light sales have been made at these low prices.

ANTIMONY

Conditions are unchanged with the market quiet at 5.25c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

The leading producer is quoting virgin metal, 98 to 99% pure, in wholesale lots for early delivery at 28c. f.o.b. plant, while the same grade from other sources, mostly foreign, is obtainable at a range varying between 23 and 23.50c. per pound, New York.

ORES

Tungsten: Demand is only fair and sellers' ideas of prices are relatively high, due to tariff uncertainties. Chinese ore is quoted at about \$3 to \$3.50 per unit, with high-grade ore correspondingly higher.

Ferro-tungsten is quoted at 58c. per pound of contained tungsten in guaranteed lump form.

Molybdenum: The market is nominal at 55 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: No business in high-grade ore is reported and quotations are nominal at 22.50c. per unit, seaboard.

Manganese-Iron Alloys: There is almost no demand for ferro-manganese which has declined to \$30, delivered, for the American alloy, with the British product available at \$75, seaboard. Spiegeleisen, 20%, has sold at \$30, furnace. About 250 tons has been sold and about 250 tons is before the market. The prevailing quotation is \$30 to \$32, furnace.

Ferro-silicon, 50%, can be bought at \$80, delivered, in almost any quantity for delivery this year.

The age-old dream of the alchemist is realized because of Linde

THROUGH countless centuries man dreamed of transmuting the baser metals into gold. Patiently, laboriously, often consecrating their very lives to the work, the Alchemists of old toiled on toward their elusive goal.

As late as 1873 James Price, the last of the Alchemists, sought death by his own hand rather than acknowledge the failure of his experiments.

Linde Engineers of to-day have made this dream of by-gone ages come true.

By producing uniformly pure oxygen in industrial volume, they have made it possible for oxy-acetylene welders and cutters to reclaim thousands of tons of metal machinery annually—turning base metal into gold—a saving in money far in excess of any vision of wealth dreamed of by ancient philosophers.

And Linde does more than supply oxygen of absolutely uniform purity. Thanks to a chain of twenty-nine plants and forty-six warehouses it delivers Linde Oxygen when and where it is wanted in any volume.

THE LARGEST PRODUCER OF OXYGEN IN THE WORLD

T. A. RICKARD, Editor

THE prophet Micah's forecast of the days when men would "beat their swords into plowshares and their spears into pruning hooks" has been more than fulfilled in these latter days by the use made of floating mines. Many of these instruments of assassination have been found on the shore of the Gulf of Finland, and refugees from Kronstadt have been fed by the American Red Cross at Terioki. The finding and the feeding are connected by the fact that the mines, after their charges have been removed and their fittings detached, have been converted into soup-pots.

'BARRON'S', the new financial paper, speaking of organized and unorganized labor, says that "The average layman will perhaps not readily grasp the incalculable increase in 'job spirit', workmanlike emulation, fellow-feeling, and man-to-man co-operation that the 'open shop' system engenders among workers. Talk to a non-union man and you almost invariably feel that here is one who has the good of family and country at heart, rather than unthinking obedience to demagogues or unfounded distrust of employers". There is much to be said in favor of the 'open shop', despite Judge Gary's truculent advocacy.

FINANCIAL participation is one of the greatest incentives to effort and to the practice of economy. The Electrolytic Zinc Company, of Hobart, Tasmania, recently made a proposal of a novel kind to its employees. Wages and salaries are to remain at the present level, but weekly deductions are to be made before payment, on a sliding scale, and ranging from 10% to 7½% of the amount earned. The deductions are to be placed to the credit of a trust-fund, to be converted into shares of the company, which will be held in the names of the workmen. Amounts below a certain minimum will be paid in cash. The proposal has been approved by a majority of the works-committee, representing all employees.

DIRECT production of articles of commercial utility in the electrolytic cells of a copper-recovery plant would greatly reduce the cost to the ultimate consumer. The work of melting and fabrication would be avoided, to say nothing of the cost of handling between the various copper-selling agencies and middlemen, all of whom exact their bit of profit, which, in the aggregate, makes

the pound of shaped copper so expensive that a cheaper and less efficient substitute is often sought. A method of obtaining a large variety of copper articles, by direct deposition from the leach solution, has been proposed; it is claimed that a smooth and satisfactory surface is practicable. Tests are to be made, we understand, at the Ajo plant of the New Cornelia Copper Company, and the results will be anticipated with interest.

IN a Texan newspaper we find an item concerning a mine that lies "between a paughfrey and a mica schist formation". This sounds almost as promising as the lode between cyanide and hootchite. Moreover, "gockets of sulphide or copper glance" have been discovered; these interesting accretions being "a secondary enrichment" containing 40 to 60% copper, and 100 to 1000 ounces of silver, "which is characteristic of this mine". Then it has a high-class character, without doubt. Indeed "Mr. O. Martin of Mexico City and Mr. Haywoodson of Helena, Montana, have pronounced this the largest deposit of copper, silver, and gold that has been developed in this country". The dimensions are not stated, but the deposit is one of unusual scientific interest. A gocket in paughfrey is unique.

THE importance of discipline in mine management was emphasized by Sir Lionel Phillips at the recent annual meeting of the Transvaal Chamber of Mines. Although it may be possible and proper to appoint committees whose purpose it is to consult with the mine manager, to discuss with him matters where men's lives, their manner of living, their working hours are concerned, nevertheless there must be someone who can assert authority in matters connected with the ordinary operation of the mine. If the mines were in the hands of the working population, they would find it necessary to have either one man or a small committee of men with absolute authority, whose commands had to be obeyed. The desire of every man to rise in the world and to better his position is a logical one; but the welfare of a man, according to Sir Lionel, can only be advanced by the efforts of that individual himself. If the workers would only take that truism to heart, and if each gave to the industry the best of his effort during the reasonable hours of his employment, a considerable reduction in the cost

of production of gold would result. As Mr. Arthur J. Balfour said, "It is a very easy thing for a government to make rich men poor; the great problem for every government is to make poor men rich". Men cannot better themselves except through their own strong efforts. If mine managers should be met with demands that are considered as unjustifiable, these should be resisted, in the interests of the working population, the industry, and the country.

PROMOTION of a better knowledge of Spanish in the United States and of English in Latin America might be furthered, in the opinion of the Minister of Guatemala, who spoke at Washington recently, by the organization of a society or league to promote the reduction of language barriers between the Spanish- and English-speaking peoples of this continent. The teaching of English is compulsory in some Latin-American countries; the extension of the use of Spanish as an item of practical education in the United States would facilitate the plan, proposed by Mr. Bianchi, to arrange for the interchange of clerks between the different countries. A real knowledge of the other fellow can only be obtained by personal contact. The thoughts and aspirations of our neighbors to the south would be all the clearer to us if, as a nation, we could understand what they have to say.

INADEQUATE remuneration of engineers is illustrated by a list of average incomes, compiled by the secretary to the class of 1910 of Cornell University. The list is headed by the bankers and brokers, whose average income is \$11,040; these are followed by 14 classes, including veterinarians, salesmen, insurance 'financiers', advertising men, purchasing agents, farmers, and builders; then come the engineers, with an average salary of \$3724—next but last on the list and before the teachers, who earn an average of \$3137 annually. Scientists and research men are probably included among the engineers, and this may account, to some extent, for the low average. The figures suggest one of two things: either some of the Cornell graduates are calling themselves engineers when they are not in the professional class, or the devotees to this branch of human endeavor are, like the teachers, being poorly paid for their services. It is interesting to note that the number of engineers in the list is more than twice as much as may be found in any other of the classified professions of occupations that are enumerated. Over-crowding may have something to do with the existing low rate of pay. The subject is one that merits discussion.

INSECURITY of tenure was the keynote of a speech made recently by Mr. Whiting Williams, the author of 'What's on the Worker's Mind', to the members of the Commonwealth Club of this city. Mr. Williams, who was formerly the assistant to the president of Oberlin college, submerged his identity and went to work for ten months last year as a common laborer in mines, mills, and railroad shops both here and in Great Britain. He was

impressed by the far-reaching effects that lack of a job or fear of losing the job have upon the average worker's mental attitude; according to him, it accounts for the spread of the doctrine of reduced production, of diminished labor. When Mr. Williams set to work at one place, carrying bricks, a fellow workman came up and enquired: "What da hell! Where da fire?" Without some sense of security in the matter of being able to maintain himself and his family, the laborer loses his spirit, and then falls an easy prey to the preachers of bolshevism; the Reds and the I. W. W. obtain their recruits almost entirely from the ranks of the unemployed. The worker needs more than his daily bread; he needs self-respect; his inarticulate prayer is "Give me this day my daily job"; and he wants a job on the morrow, too. Social and industrial conditions in Great Britain are in a parlous state, according to Mr. Williams, who found more unrest and bolshevism there in seven days than he had observed in the United States in as many months. He compared the conditions at Middlesborough, the Pittsburgh of Great Britain, where employment is regular and where the workers are properly housed, with the conditions in Glasgow, where work is irregular, where social conditions in a certain stratum of society are unmentionable, and where Mr. Williams found that in some parts of the city, a man or a woman who did not stagger with real or assumed drunkenness on a Saturday night would be looked upon with suspicion. Irregular jobs make irregular workmen; irregular workmen make irregular citizens. Mr. Williams' sincerity was evident, his impressions had been formed as the result of an actual experience that gives them weight; he has drawn attention to a phase of the relations between employer and employee to which more attention might well be paid.

COMBINATIONS are liable to result in an unfair restraint of trade, hence the legislation against this form of business in this country. In Chile, an association of producers has been successful in raising the market price of nitrate to such a point that sales have declined to a level that is causing some concern to the Government, which obtains a large proportion of its income from the export tax on nitrate. President Alessandri is now asking his congress to approve a plan to nationalize the sale of nitrate. This plan, if consummated, will kill the present export tax; the profit from the transactions will be divided between the Government and the producers. However unwelcome such interference, the producers have only themselves to blame. The reduction in the price, which would automatically follow the adoption of such a plan, would benefit all concerned; the maintenance of the high-price level has been one of the reasons why little attempt has been made to improve the percentage of extraction or to reduce the cost of production. In spite of small-scale operation and inefficient beneficiation, big dividends have been paid to the stockholders in nitrate companies, a circumstance that has been due largely to the impoverishment of large areas of nitrate-bearing ground by the selective mining of high-grade caliche only. The idea has been to grab

profits while the grabbing was good. The Government is now waking up to the economic waste involved, a waste that, to the producers who are scared with the bogey of cheap synthetic nitrate, is of no moment. President Alessandri's initial action in the matter is doubtless only a preliminary to drastic governmental interference; it should do much toward removing a serious restriction against the sale of a product that is in urgent demand at the present time. It will lead to a consideration of whether the Government should or should not concern itself more directly with the methods adopted in working the deposit, in an effort to minimize the wastage of a national asset.

NOT enough notice has been taken of the decision made recently in the case of the Rochester clothing industry. It appears that the wages of 7000 workers were affected by this decision, which was the result of an arbitration placed in the hands of a Dr. Leiserson. He authorized the transfer of all the workers in the Rochester men's-clothing industry from a day's-pay to a piece-work basis. Those who worked by the week were making 20% to 25% less than the piece-workers, whereas the cost of labor per garment was greater under the week-work than under the piece-work system. Dr. Leiserson held that the economic motive to increase earnings would be a decisive factor in decreasing the unit-cost, and would prove more advantageous to the manufacturer as well as to the worker, than a reduction in wages without an added incentive to production. This, of course, is entirely in accord with the experience of those who have charge of mines in which the contract system enables the men to earn more while at the same time decreasing the cost per ton or per foot, whatever the unit of measurement. The one reason why the contract system fails, as it has in many mines, is because it is applied unfairly to the workers. In these, as in all economic engagements, a spirit of fair play is fundamental.

WE sympathize with the young college graduates who were declared to be "grossly ignorant" by Mr. Edison because they were unable to answer satisfactorily a catechism of 77 questions propounded, by the so-called wizard of East Orange, to recent applicants for positions in his laboratories. Obviously the intent of the questions was to determine the character and extent of the candidate's reading, and the receptiveness and retentiveness of his mind for general information. However, many of the questions concern trivial historical and geographical facts, easily ascertainable in two minutes by reference to any encyclopedia, but with which few men attempt to clutter their memories. Another kind of question deals with semi-technical information that is entirely well known to specialists in particular industries; but to expect all, or nearly all, of these queries to be answered off-hand by a young man is hardly reasonable. Some of the questions are not open to precise answer, for example: "In what State are located our chief copper mines?" Most mining engineers would say Arizona; Mr. Edison had

Montana in mind. He, doubtless, had all the information contemplated in this questionnaire at his finger-ends; however, we should like to prepare a set of queries, different in detail but identical in general character and submit them to him. With all due respect for Mr. Edison's unusual attainments, we believe he would have to exert himself to make a perfect record; and, we venture to surmise, he might re-appraise the abilities of some of the recent aspirants for modest jobs in the Edison organization. During the War young officers were subjected to sundry peculiar mental tests designed to determine the alertness of their minds, and the quickness, keenness, and accuracy of their thinking. The men who passed these examinations with exceptional success almost invariably made good officers. The ability to store away a lot of miscellaneous information in the files of one's memory and to refer promptly to isolated facts when required is an asset; but the mind that is too busy with memorizing has little time left for thinking.

A CORRESPONDENT in the 'South African Mining & Engineering Journal', reminiscing with reference to a prospector to whom he was able to extend a kindness that was remembered in later years, says: "He was very ill and knew that his end was near. He called me aside and told me that in return for what I had done he wished to tell me something important—that in a certain place that he described minutely he had found rich reef gold. When he discovered the reef he had no money to peg and hold, so he covered up his work and remained silent. A rush took place over another field in that locality and his reef was covered by the pegging. The ground was held for 25 years, off and on, by people who, he knew, were not likely to give him much recompense for his information. He was never one of the lucky prospectors, and preferred to go to the end very poor rather than to disclose his find to the Johannesburg financial 'sharks', as he called them." Such a sentiment, we would add, is found not only in South Africa, it is in evidence elsewhere and in many other branches of endeavor. Prospectors are human; they have a natural repugnance to giving up everything and getting practically nothing in return; many become soured by the inconsiderate attitude of the promoter with whom they do business. The correspondent to whom we have referred makes a pertinent and timely suggestion toward aiding in the opening up of new mining districts and to encourage the prospector and small-mine owner. He suggests the formation of Government banks, for the purpose of giving financial assistance to those in need, with a limit of from £3000 to £5000 advance on any one property. These advances would be the first charge on operating income, and would be granted only if sufficient gold were developed; the money would be issued solely for the purpose of financing the erection of a treatment plant. The district that contains the contented prospector and the prosperous small-mine owner is likely to have a future. The plan, if adopted, would help to encourage the search for new goldfields.

Ventilation and Miners' Phthisis

In a recent issue we drew attention to the factor of humidity in the question of mortality or sickness among mine-workers; in the report from which we quoted it was mentioned that the death-rate among employees who were working in a humid atmosphere was much higher than among those who were working in a dry atmosphere, the humidity in the former case being the result of efforts to allay the dust that arose from grinding and polishing operations. We came to the conclusion that, although the development of the tubercle bacillus is hastened by environment in a humid atmosphere, in most cases it is considered that the good done by allaying the dust in a mine more than counterbalances the ill effects of increased humidity. The time has come, however, when it should be recognized that the allaying of dust underground is not the ultima Thule of preventive measures against disease in general and tuberculosis in particular. In many mines insufficient attention has been paid to the subject of good ventilation, and this is the reason why tuberculosis, when once developed among miners, progresses into the 'galloping' stage so frequently. In a paper read recently before the Chemical, Metallurgical and Mining Society of South Africa, Mr. C. J. Gray, the chief Inspector of Mines for the Johannesburg district, emphasizes this fact. According to him, the reason for the apparent apathy on the part of South African mine-owners is generally monetary. The purchase and maintenance of fans involves considerable expense. For many years, on the Rand, spraying was optional; even now fan ventilation is optional, and the distribution of air is haphazard. A manager who tried to better conditions underground would find his costs increasing; head offices would naturally compare the expenses with those on mines where no such work was being done. The desire for improvement would thus be stifled at its source; apparently legislation is necessary. Lack of ventilation, according to Mr. Gray, is at the root of the trouble; it is largely responsible for the conditions of ill-health among underground workers. The adoption of such improvements as sprays and atomizers, wrote another observer in 1906, merely indicates that the evil is being played with. Water is only a palliative; ventilation is the cure by which a clean bill of health can be secured. We read in the preliminary report of an investigation that was made on the subject of miners' consumption in the mines of Butte, Montana, and recently issued by the Bureau of Mines, that "in most of the working places examined in Butte the temperature was well above 70°F., little or no movement of the air was perceptible, and the humidity approached saturation. Comparatively little work in such places causes body temperature quickly to mount from 98°F. (normal) to 103° or higher—that is, to fever temperature. The immediate effect of such conditions is greatly to decrease the working ability of the men. It is the impression of the authors of this report that in the places visited the time spent in actual work during an eight-hour shift was not in excess of four to five hours, and was probably much less. An adequate

movement of the air, even if it did not lower the temperature, would greatly increase the efficiency of the men". We are inclined to query the general statement as regards rise in body temperature under such conditions; nevertheless the report deserves consideration. The two signatories to the report make a number of suggestions, particularly as to how effective ventilation can be secured; they recommend a more extended use of doors, of fireproof canvas and brattice, and of regulators; on haulage roads a type of door should be used that can be relied upon to close automatically and that will allow a minimum leakage of air; all mines should be ventilated by means of fans.

It is significant that although the investigations were concluded in 1919, the report, a pamphlet of only 19 pages, did not appear until recently. This indicates, apparently, the congestion of printing work at the Government offices in Washington. It is regrettable that reports of value, containing definite recommendations for the amelioration of unsatisfactory conditions, cannot be printed and distributed prior to technical reports on unimportant matters and of only local interest. Between the time of the investigation by the Bureau of Mines officials and the issuance of the report, Mr. A. S. Richardson, the ventilation engineer for the Anaconda Copper Mining Company, published an account, in the 'Anode', of ventilation in the mines at Butte; he detailed the factors that control or influence the conditions that have prevailed in the past and will prevail in the future; and he outlined the steps that are being taken by the company to ensure, as far as is possible, the satisfactory ventilation of, and the reduction of temperature in, the underground workings. From this account we learn that, in the Butte mines, the rock temperature may be as high as 104°F.; the heat underground is also partly due to the 'oxidation' of the mine timber, which is used in large quantity. The problem has been considered in all its details. It was found that resistance in the shafts, due to the open framing of timbers, retarded the flow of the air. The shafts have been lined with cement slabs and the faces of the timbers have been covered. The volume of air circulating, per man, amounts to more than 400 cubic feet per minute; 600 cubic feet per man per minute will be obtained when all the equipment proposed is in operation. It is pointed out that the laws governing the ventilation of both the bituminous and anthracite coalfields of Pennsylvania call for the circulation of 200 cubic feet of air per minute. Difficulty has been experienced at Butte in maintaining air-tight the ventilation doors and bulkheads. Lower-level ventilation is to be ensured by 'booster' fans, 200 of which will be used in the company's mines when they are all in operation. In short, it seems that the Anaconda company is taking steps to remedy the conditions mentioned in the Bureau of Mines report; it has always been the policy of the company to take such action; it is 'good business' to better conditions that are unsatisfactory. The importance of the subject will be realized when it is mentioned that of 1018 miners

at Butte that were examined between 1916 and 1918, no less than 432, or 42.4%, were found to be suffering from phthisis. Continued attention to the problems of dust-allowing and ventilation, coupled with the enforcement of a restriction that tuberculous men should not be permitted to work underground, will do much to reduce infection and to prevent the spread of the disease.

The Railroad Problem

The railroads may be likened to a very sick man. As to this there is general agreement; the fact is also accepted that, in the public interest, the sick man must not only be kept alive but must be restored to normal health. However, as to the exact cause of the illness and the best remedy to be applied, opinions differ widely. The Senate Committee on Interstate Commerce, of which Senator Cummins is chairman, recently started an investigation to determine how the railroads got into their present predicament and how it might be possible for the Government to assist them. In opening the inquiry Senator Cummins stated that the net operating income for the year ending March 1, 1921, was only \$2,578,922, as compared with \$787,610,435 in 1913. It is obvious that 2½ millions does not represent a reasonable return on the capital invested in railroad property. Statistics presented by Mr. Julius Kruttschnitt, Chairman of the Board of the Southern Pacific company, show that the volume of traffic during 1920 established a record never before equalled. The freight movement amounted to nearly 450 billion ton-miles; the passenger traffic totaled 46 billion miles; and the freight-rates averaged 1.104c. per mile, as compared with 0.55c. in 1913 and 0.974c. in 1919. The gross operating income for the year ended March 1, 1921, was \$6,175,962,000. But on the other side of the ledger is found an entry of \$5,825,388,510 as direct operating expense, to which must be added taxes and miscellaneous charges before calculating the net income of about 2½ millions. During recent months unquestionably there has been marked industrial stagnation; production has fallen off and railroad traffic has decreased. However, for the period under consideration, the statistics cited show that the volume of traffic was at the peak, that the rates were the highest since the Interstate Commerce Commission was created, but that in spite of these favorable factors there was practically no profit. Senator Cummins defined the situation clearly when he said: "The problem before us is to ascertain whether the six billion dollars received as operating revenue . . . was wisely, economically, and effectively expended." The only alternative to a reduction in operating cost would be an increase in freight-rates, which appears to be inadvisable even to the railroad managers. Those who have goods to ship contend that business is being strangled by the high rates and that a reduction is imperative. The railroad executives maintain that the existing rates have had little to do with the present business depression; they contend that many commodities would not be shipped even though the railroads offered to move them free of charge. Although this is literally true at the moment

with respect to certain raw materials for which there is no immediate market, the general principle that an excessive cost of transportation will hamper industry seems unassailable. At the same time the executives of the railroad companies do not deny that sundry adjustments downward are advisable; doubtless they see the advantage of making a voluntary reduction to stimulate particular classes of traffic in preference to facing a horizontal decrease by order of the Interstate Commerce Commission. The recent decision to reduce the trans-continental rates by 20% in order to compete with the cost of all-water shipments by way of the Panama Canal is an illustration.

If, as seems certain, no great increase in revenue over that of 1920 can be expected, the obvious solution of the problem lies in reducing expenses. Mr. Kruttschnitt concedes that the trouble with the railroads is excessive operating expenditures, of which an "abnormal amount" is represented by the cost of labor. Had the increases awarded by the Railroad Labor Board in the middle of 1920 been in effect during the entire year the total disbursement for labor would have been 3980 million dollars; actually it was 3742 million, as against approximately 1700 million in 1917. He illustrates the evils of the re-classification, of the rulings in jurisdictional disputes among the crafts, and of the regulations put into effect in 1918 with respect to overtime. He enumerates dozens of instances in which absurd claims for wages have been allowed under the provisions of the national agreement made during the period of Federal control. However, neither these unjust rulings as to wage-payments nor the huge total represented in wages has any bearing on the establishment of a fair wage-scale. The railroad managers, nevertheless, maintain that a reduction in wages is warranted, first, because it is necessary in order to cut expenses; second, because it is justified by the reduced cost of living; and third, because it is possible to hire men in the open market for much less than the rates provided in the national agreement. The managers declare that they have no quarrel with their employees, but that their aim is to promote "a friendliness and co-operation which will result in work at satisfactory wages for the largest possible number of men, and in an efficient and economical service to the public". To this attitude no one can take exception.

The employees, on the other hand, particularly the union brotherhoods, declare, through Mr. W. Jett Lauck, a self-styled economist, that expenses can be reduced sufficiently, to assure the necessary excess of earnings over the cost of operation, by efficient and economical administration without any alteration in the wage-scale. They allege that the railroad companies purchase fuel, material, supplies, and equipment from concerns owned by the railroad interests, at exorbitant prices, the money finally coming back into the hands of the controlling stockholders in the form of profit from the vending concerns. This charge is called "absurdly untrue" by the railroad executives. The old argument based on presumed over-capitalization of the companies is ad-

vanced to show that they are endeavoring to earn a return on fictitious capital never actually invested. No one denies that years ago a great deal of 'water' found its way into the stocks of some of the railroads, but, taken as a whole, the railroad systems of the country are not greatly over-capitalized, as is indicated clearly by the data already obtained by the engineers of the Commerce Commission in their survey for a physical valuation. It is also contended that increased rentals for dwellings have more than offset any decrease in the cost of other necessities. In any event, the Labor Board has announced that wages for common labor will be reduced by from 10 to 15%, the new rates to become effective on July 1 next; this will be followed no doubt by further readjustments for all classes of employees, based on the decision that the cost of living has actually decreased during the last year. According to the U. S. Bureau of Labor this decrease amounts to slightly more than 30%.

Mr. Kruttschnitt suggests other remedies which he said were "easily applied and productive of great economies". He discloses the existence of two grievances; one is against the motor-truck, the other against the Panama canal. His attitude is typically that of the 'railroad' man; as is natural, he can see only the railroad side of the question; he does not realize that, if certain kinds of traffic can be handled more efficiently and economically by motor-truck or by cargo-ship, it is not in the interest of the public for the Government to make laws for the purpose of artificially diverting such traffic to the railroads. At the same time the railroads offer definite advantages over any other method of transportation, their welfare is vital to the industrial prosperity of the country, and they must be maintained for efficient service. Mr. Daniel Willard, president of the Baltimore & Ohio railroad, declares that private ownership cannot last if the operating results of 1920 are not improved upon in measurable degree. The alternative is Government ownership or at least Government operation. Like every other branch of industry the railroads are suffering from the general depression. This, however, is but temporary, and when the reaction comes private management will be put on its final trial. The Interstate Commerce Commission, while it fully appreciates the gravity of the situation, can remedy it only by increasing rates, and increased rates do not necessarily mean increased revenue. Every increase in the cost of transportation by rail obviously widens the field for successful competition by motor-trucks and ships; it has a sure tendency to decrease the margin of profit on commodities in general, and thereby to decrease traffic. The Labor Board has indicated already its policy to give what assistance it can reasonably and justly; Congress is willing to help, but can do little; the outcome appears to depend finally upon the railroads themselves and their administrators. They can no longer shift the blame for everything bad onto the shoulders of the erstwhile Director General of Railroads. Although the experience of the two and a half years preceding March of 1920 is not reassuring, the fact remains that Government operation with unified control

has distinct advantages that offset to some extent its proved shortcomings. It remains for the railroad executives to show the public that they can run their business profitably in fair competition with other forms of transportation, and without resort to the old abuse of discrimination against one community or one commodity because the 'traffic might bear it'. Apparently the taxpayers would rather support the railroad under Government control, with all its faults, than support them indirectly by guaranteeing 'standard' returns to private owners. If the officials succeed in operating their roads effectively and efficiently, private ownership is likely to survive; otherwise the remedy is plain.

Education for Miners

Educational facilities, in the various mining schools of this country, have increased to an undesirable extent, according to Mr. H. H. Knox, whose comments on the subject appear in the current bulletin of the Mining & Metallurgical Society of America. The acquirement of a higher education has been so easy that many a good mechanic has been spoiled in the making of a poor engineer. The principle underlying such higher education, in Mr. Knox's judgment, compares unfavorably with what is considered desirable in some other countries. The university here is but the extension of the high-school. "The pupil enters, remains, and finally departs, through the gateways of examination; his sole aim is a degree. In short, the university is essentially a mechanism for attaching diplomas to young men; and it is indeed fortunate if, after the accomplishment of this act, the jaded faculty has any time or spirit left for original work and contributions to learning." Mr. Knox sees a need, in our university system, for the provision of educational facilities for extra-graduate students, regardless of age, station, or education, who may desire instruction in any subject whatsoever, and whose time available for such work may vary from four days to four years. The student should be the only judge as to his own needs. If such arrangements could be made, little alarm need be felt that the privilege would be abused. As Mr. Knox says, "the hunger for knowledge is not yet a public menace; there is small danger of an unwieldy 'bread' line". The suggestion is worthy of consideration. The well educated man, we would affirm, owes his mental equilibrium to his acquisitiveness, not because, by temperament or training, he has been merely receptive. Originality and initiative are the best indices as to whether education is 'taking'. An altruistic desire for enlightenment may come long after college life has passed, long after a degree has been gained for proficiency in the memorizing of facts and theories. If our universities could help in the encouragement of this most important branch of higher education they would be performing a notable service to themselves, as well as to a part of the community deserving encouragement in the consummation of a natural desire to climb to a position where scientific research may be undertaken.

DISCUSSION

The Colorado School of Mines

The Editor:

Sir—My attention has been called to a letter from D. H. Fairchild published by you in your issue of March 26, under the title 'The Colorado School of Mines'. As an alumnus of the school, I feel it my duty to correct, if possible, some of the misstatements it contains and if it is not too late I humbly beg the privilege of doing so at this time. My delay in sending in this communication was occasioned by an indecision in my own mind as to which would benefit the school the most, an answer to your correspondent's letter or simply ignore it. The School has suffered unjustly from too much talk in the public press from those who when pinned down to the facts have to 'pass the buck' and say that some one else told them. At the present time the School is in better shape than it ever has been since I first became acquainted with it when I entered in 1908.

The statement contained in the second paragraph of the published letter that Mr. Lee, who acted as attorney for the president, trustees, and faculty, at the request of some of the alumni and friends of the School, classed President Alderson with Washington and Lincoln is, of course, ridiculous. What he did was to draw the attention of the committee to the fact that it all too frequently happens in American public life that honest, energetic, faithful, and successful public servants are made the subject of vicious and unfounded attacks. He called attention to the recent experience of Charles M. Schwab, who served as a 'dollar-a-year man', and in like manner to the libelous statements that were given wide circulation with reference to Washington, Lincoln, Grant, Cleveland, McKinley, and Roosevelt, taking merely the familiar instances that are, or should be, known to all men of general information.

It is perfectly true that he characterized the evidence as "hearsay", and what was not hearsay was of such trivial nature as not to warrant consideration by any committee of responsible men. You will note in reading the letter from your correspondent that while it is stated that "considerable evidence was submitted that was not at all favorable to the defence and was of such a nature that the committee cannot dismiss it as hearsay", such evidence is not mentioned in that letter, which proceeds to discuss the experimental mill at Golden and to give the impression that that plant was of no practical use. Two of the members of the Legislative Committee were practical mining men of large experience. They heard all of the evidence and made personal examination of the

mill, and came to the following conclusion, which will be found in their report to the State Legislature:

"It has been indicated in the testimony that this experimental plant was useless. This opinion, your committee must utterly disregard. Your committee thinks it is useful and that it can be made of very great use to both the School of Mines and the mining interests of this State, if sufficient funds are provided to complete the plant in accordance with the original plans prepared and submitted, supplemented by changes which may be necessary to make at this time, in order to bring said plant to up-to-date practices and in full conformity to the needs of the School."

Your correspondent did not include in his communication any reference to the testimony of an engineer representing one of the largest corporations in the country, who has been for many months past and is at the present time making constant use of this experimental mill in ore-testing, and who testified that it could be used practically and efficiently.

Your readers may or may not have noticed the significance of the statement contained in the letter that "a bale of telegrams from various mining companies and other sources was submitted". These telegrams were statements that the graduates of the Colorado School of Mines were competent and efficient, and adequately educated men, whose work was satisfactory to the companies employing them. They came from the biggest mining and engineering concerns in the country. This would seem to me to be the final test of an institution of this nature.

Your correspondent is correct in saying that Mr. Lee, in his closing argument, criticized Mr. Lunt and the writer of that letter for their excessive interest in the promotion of the attack upon the Colorado School of Mines. Mr. Lunt is Commissioner of Mines to the State of Colorado, and admitted on the witness stand that he had absolutely no personal knowledge of the conditions as to which he was appearing to testify; yet without any personal knowledge he was willing to repeat unfounded slander. Mr. Fairchild's attention to the affairs of the School is sincerely appreciated, but we marvel that a graduate of the Rolla School of Mines should be so willing to condemn the Colorado School of Mines and its experimental plant. Then, later, without waiting for the report of the committee, to burst into print, this time not only criticizing the School but going farther and criticizing the method that the School used in defending itself before the Legislative Committee. This profound attention "passeth all understanding", until it is known that

Mr. Fairchild shares an office with one of the professors who, upon the re-instatement of Dr. Alderson as president, sought the court to restrain the trustees from appointing him.

The gentlemen mentioned in his letter, Messrs. Taylor and Wells, both admitted upon the witness-stand that they had no personal knowledge with regard to conditions at the School of Mines. Notwithstanding this fact, Mr. Taylor volunteered the statement that the recent graduates of the School were not competent men, but admitted upon cross-examination that he had no acquaintance with more than from five to ten men during several years last past, and plainly demonstrated that he had no means of knowledge as to whether these men whose reputations he was willing to blast were properly qualified or not. Such was the general character of practically all the testimony offered before this Legislative Committee, and such only is the basis to the libels that have been circulated with reference to the School.

The testimony on this hearing was taken by a court reporter and has been transcribed, and is available for anyone who seeks to investigate its nature. The report of the Committee cleared the School, its president, trustees, and faculty of all of the so-called charges made against the institution and its governing officers. The report of that committee you apparently have received. The report was made only after a painstaking investigation consuming several weeks of time, in which every conceivable type of evidence offered on behalf of those opposing the management of the School was heard with almost incomprehensible patience, and in the course of which investigation the Committee visited the School, inspected the plant, and interviewed the students and faculty. Your correspondent mentioned that, with the faculty and trustees present, the students were willing to testify that everything was in good shape. To quote him, we read: "This testimony might have been given under duress." He fails to mention that when the Committee visited the School they met the student body without a member of the faculty, trustees, or the president present. At that time the Committee invited any individual student or students that had any complaints to meet them either publicly or privately. This invitation to register a complaint was unanimously rejected.

In your opinion, ought this investigation and report put an end to the publication and circulation of the irresponsible reports of men having no knowledge of the situation to which they refer in their correspondence? The reputation of the Colorado School of Mines has been excellent and has been world-wide. It seems to me that no fair-minded man who would take the trouble to investigate or to familiarize himself with the record of the investigation just concluded could credit further disparaging reports with regard to the institution to anything other than malice or personal spite. To the disinterested such a conclusion would seem inevitable.

This letter is written with the hope that before publishing further reports with reference to conditions at the Colorado School of Mines you will make investigation as

to their basis and fact, and that you will give it the same publicity given to the criticism referred to.

Denver, May 12.

S. POWER WARREN.

[We are, of course, entirely willing to publish this letter, as the writer ought to know. We did avail ourselves of the opportunity to investigate the conditions obtaining at Golden, as Mr. Warren ought to have known before suggesting that we knew nothing about the matter. The present writer was at Golden soon after the rumpus in 1917 and made careful enquiries at Golden and at Denver. The chief trouble with the Colorado School of Mines has been due to the fact that the alumni have not been in agreement on the chief issues involved in the long-drawn wrangle. Many of them dislike Dr. Alderson intensely, probably just as many support him cordially. We gave a fair summary of the Legislative Committee's report in our issue of April 23; it is not our fault if Mr. Warren is unaware of this. It seems to us that if a committee of the State legislature reports approvingly of Dr. Alderson's administration, there is nothing more to be said by those who are not citizens of Colorado. Mr. Warren may rest assured that we shall avoid the subject henceforth; it has ceased to be interesting.—EDITOR.]

Prospecting

The Editor:

Sir—I have read your very interesting address on prospecting delivered at Portland, and your invitation to the prospector to tell what he thinks of the future of prospecting. The following is in reply to your invitation.

It is hard to say what the future of prospecting will be, but whatever it is it will depend a whole lot on what we think it ought to be. I will state in this letter what I think it ought to be, and what I think ought to be done about it.

Your address calls to mind a number of points that I have been turning over in my mind for some time. At one place in your address you state, "What is wanting today is the link between the prospector and big capital, namely, the local storekeeper and merchant who used to back the man in the hills by grubstaking him, by giving him credit for supplies, and even by putting up cash when necessary". There is no doubt but what the local storekeeper has in the past lent valuable assistance to the prospector; but there is another side to this question. The local merchant, as a rule, is not an unbiased party in the promotion of the mining industry in his locality. As a merchant, he should be interested in steering capital against the best properties in the district; but as an owner of mining claims himself he is interested in steering capital against his own properties, which may not, by any means, be the best in the district. These interests conflict. The merchant, being in closer contact with capital, puts the regular prospector at a disadvantage. It frequently happens, as many a prospector can tell you, that a mining man coming to look at a prospector's property is sidetracked, simply because he happens to meet

some local merchant or a local mining man at the club or at some hotel.

Elsewhere in your address you state, "the local wise men are likely to be better judges of a local prospect, if they have no financial interest in it". An unbiased local wise man is a rare bird, indeed. If he does not happen to have an interest in the property that is to be examined, he generally has an interest in some other property. This gives him an interest in 'knocking', to a man who has money to invest, all other properties but his own. The knocking of the local wise men is no uncommon thing; it is constantly being done, to the great detriment of every mining community. What every mining community needs, as much as anything else, is disinterested merchants and local wise men. If every merchant had no other interest, except his own business, he would be interested in seeing that every prospector got a square deal; he would try to direct the investor to the best prospects in the district.

Speaking of future mineral production, I don't believe that paying mineral is as scarce as many seem to think. It is probably true that most of the high-grade stuff has been worked out, but this is only a drop in the bucket to what remains. The first mines to be worked in nearly every mining district are the richest and the poorest. The richest because they will pay big with very little trouble, and the poorest because the wild-catter can make more money by promoting a poor property; he can get the poor property for less. There generally remain a lot of properties of average grade that can, with good management, be made to pay. The average-grade properties are more plentiful than the high-grade, and have far more mineral in them. Besides this, there is a lot of undiscovered mineral in every district.

What is needed to work these average-grade properties, as they should be worked, is a thorough prospection of all veins in a district, in order that the best may be found and worked on. That, and more good managers. The purpose of prospecting, other than finding mineral, if carried out rightly, is to eliminate the poor prospects—unpromising prospects—with the idea of working the best. The enormous amount of labor wasted unnecessarily on working wild-cats and through general ignorance is sickening, when one thinks of the enormous amount of good it would do if directed properly. Bad mining laws are also responsible for a lot of unnecessary work being done. Take, as an instance, location and assessment work. For the most part it is useless; it is labor wasted; it gets no forwarder. No more work should be done on any prospect than to determine its comparative value, so eliminations can be made. Or take the location laws, as another instance, which, by causing many different veins to be owned by many different people, induces a lot of work to be done on worthless claims, and a lot of work to be done before it is needed. The location laws cause all mineral to be placed under many different ownerships; the work is scattered, much being done on worthless claims, instead of being concentrated on the best claims where some good can be done. What we want

to do is to work the best claims first, and to work the best always. This can't be done by the way things are arranged at present.

You speak of the romance of prospecting. We are very apt, in talking about prospecting as we see it today, to see only one side of it, the bright side, and not see the tragedies of it. We are very apt to see only the great rewards that a few have gained, but to ignore the many it has practically ruined. For every one it has rewarded greatly I can show you a hundred it has treated shabbily. In this, as with gambling, we hear a great deal about the big winnings, but very little of the harm it has done. The trouble is, the prospector's pay-days, though they may be big, are too few and far between. A few owning the very richest claims, if they find them early in their lives, get their reward early, early enough to do them some good; but the vast majority have to wait from 10 to 40 years before they get theirs. And it may be a small reward at that. When they do, it is generally too late to do them much good. Their age and the life they have led has destroyed their capacity for enjoying it. Ten thousand dollars would do them just as much good as a million. A billion dollars wouldn't pay them for what they have lost; nothing would. Our wants are so distributed that we have to live as we go along, if we are to get much out of life; and our rewards, for that reason, must be distributed accordingly. What is needed is a system of distributing risks and rewards, whereby a prospector can get some of his reward as he goes along, instead of waiting until some time in the distant future, when he has no great need of it.

You state, "public opinion in the United States is opposed to the payment of direct monetary subsidies to prospectors". So am I, and, what is more, I am opposed to subsidies from any other source. I believe prospecting should stand on its own pins, just as every other business should; I believe that prospecting should be supported by the proceeds of prospecting, from the sales of prospects, or at least by the mining industry, instead of being supported by merchants who must add what they have lost to the cost of what they sell. As things are conducted at present no track can be kept of what things actually cost to produce. Let the prospector do the prospecting, the miner do the mining, and the merchant the merchandizing. By such an arrangement prospecting, and all other business, would gain immensely by being conducted by those who understood the business. Such an arrangement would also cut the wild-catter off at the pockets. The wild-catter preys on the ignorance of the people.

You state that "risk is the essence of mining, risk with a chance of more than adequate compensation". Risk is a large element in any business, but in mining it is probably larger than in any other. Good mining consists in reducing this risk by a better knowledge of mining and risking the rest, which risk may be distributed and shared by many, by means of better organization. The element of risk in mining will always, in all probability, be very large, no matter how scientific we get;

mining will always need adventurous spirits to carry it on.

Risk in any business may be distributed in two ways: (1) By dividing the business into stages. Mining is naturally divided into three stages, the prospective stage, the speculative stage, and the productive stage. These different stages, if conducted by distinct groups, distribute the risk, and make the pay-day come oftener than if one group carried the whole operation through all the different stages, which is not often done. It can only be done with a rich property, and by big capital. Also, this division of labor, which makes for expert knowledge and labor, would lessen the risk. (2) The risk is distributed by causing it to be shared by many, through larger organizations. In these two ways, the evils of too big a pay-day (it is an evil to have more at one time than is really needed) and too long a pay-day will be avoided. When we get right down to the bottom of things, isn't the biggest problem in life the distribution of the inequalities of things—the burdens—over time and space—absorb the shock from bumps and smooth them out so things will ride a little easier and safer.

Speaking of distributing risk, by dividing mining into stages: It often happens, for various reasons, principally financial, that one man or a company can't even carry one of these stages through to a successful conclusion; they have to drop the work before they are through. Then someone else comes along, takes up the work where the other left off, finds something, and reaps the reward and the credit. This often happens in prospecting, and just as often in developing a mine. This injustice, which, probably, isn't anybody's fault, must be attributed to faulty organization. A fine example of this is found in the development of the Little Daisy or U. V. X. J. J. Fisher, the first manager of the Little Daisy, and the people he represented, did the pioneer work. To them a great deal of credit is due, which they have never received. They revealed a mineral condition that any mining man would take as a first-class guide in further exploration. Fisher without a doubt suffered greater disappointment than anyone ever connected with the Daisy. His death was to a great extent due to the ups and downs of its development.

All the obstacles to good mining mentioned in the foregoing are due to faulty organization. Many individuals and many small organizations working in as many narrow fields can't possibly carry on mining, or any other business, without a great deal of risk and loss, or without a great deal of inconvenience and suffering, and, in many cases, without lasting injury. Mining cannot be carried on in a scientific and business-like manner, or with comparatively little inconvenience and suffering, except by big organizations with big fields to work in—the bigger the better.

The ideal prospecting condition would be to treat all mineral as if it was in one vast group of mining claims, owned by one big prospecting company. Of course, it is to be understood, it is not thought that such an ideal arrangement can possibly be realized very soon. It is

only advanced as being a goal to drive for, something to be consummated in the distant future: as something to remind us that, whatever our prospecting troubles, most of them are due to the lack of these ideal conditions.

The following is an outline of a plan of prospecting developed while I was working for a big mining company in Central Africa. It, undoubtedly, can be much improved, but it will serve to show how, by some such method, much more easily and more quickly really essential information can be gained where an extensive region is prospected by one big company. The plan here described applies to conditions as they exist in Central Africa.

Where a large territory is to be prospected by a few men in a limited time, a selection of the best ground should be made before or at the expiration of that time, and a part, possibly, exploited during that time. It is necessary to adopt some method of prospecting whereby the best ground may be found in the shortest possible time. We have conditions something like these on a mining concession. I can describe a method that, I think, will accomplish the desired results.

To have a clear understanding of this method it is necessary first to state some facts concerning the distribution of gold. (1) The most gold is found on or near bedrock. This is due to the force of gravity. (2) The coarsest gold is found along the shortest path water can take in passing down-stream. The pieces decrease in size as the path gets longer or passes to one side. Where the richest ground will be found depends on the size of pieces composing the bulk of the gold. If composed principally of fine gold, the best may be found considerably one side of the straight path. This rule will, of course, be modified by the structure of the bedrock; but on the whole it is safe to say that the most gold will be found near the shortest path. The shortest path has the steepest grade and the swiftest water; the curved path has less grade and the slowest water. The coarse gold being carried down by the swifter water above will be deposited a little to one side of the straight path when it enters the slower water of the more curved path, leaving only the finer gold to be deposited along the curve. On the other hand, when the stream takes the straight path the water flows faster, taking with it the coarse gold, which may reach bedrock or be deposited in the gravel at or near the swiftest part. The coarse gold is found at or near the straight path because the swift water is the only water capable of moving the coarse gold. The swift water of the straight path also helps free the gravel of fine sand, leaving the coarse gravel, which may be taken as an indication of the best ground. The coarsest gravel is along the straight path for the same reasons the coarse gold is there. The prospecting maps show that, as a rule, the richest ground is found near the straight path.

(3) The richest and poorest ground, respectively, are found in the small branches or heads of streams, because they may be entirely in goldbearing and non-goldbearing rocks. There is less chance of having rich and poor

gravels mixed, as is the case in the lower parts of streams. Also the swift water, due to steep grades in small branches, frees the gravel of the finer stuff. (4) Quartz gravel, with which the gold is usually associated, is lowered in value when mixed with other gravel, such as diorite, diabase, schist, particularly schist impregnated with iron and hematite. As much as 95% of the gravel is quartz in these African streams. This is due, no doubt, to the fact that, being in a region of abundant rainfall and vegetation, and with a tropical climate, all minerals except quartz and quartzite are easily decomposed. (5) The lower parts of a stream system are usually not as rich as the upper parts. This is due to a more thorough distribution of the gold throughout the whole deposit, on account of its fineness, and to the mixture of the poor and rich gravel of the upper parts. Gold in the large streams of a district, though not in paying quantities, may be taken as good indications of the possibilities of the small streams flowing into it. (6) As a rule the best placer is not found in or near the valleys, nor are the veins so well exposed as in the mountains.

Any method of prospection must take advantage of these facts of gold distribution in order to accomplish the best results. Prospection should proceed as follows: First, it should begin in the mountains. Second, the streams in the mountains should be prospected by cutting across them in many places. A number of holes at, above, and below the point of intersection of the route will give a fair idea of the value of the ground, and the possibilities of the upper parts of the stream. A better idea of the value of the ground in the lower parts of a stream can be gained with a few holes, on account of the better distribution of the fine gold, than can be gained in the upper parts, in which the distribution of the gold is usually irregular. This prospection will indicate what streams have the greatest possibilities, also, some idea of its accessibility, food supplies, and the routes would be gained. Third, selecting the stream which is thought to have the best possibilities, accessibility and food, follow it up, taking samples at different points, also surveying it. Where a stream is found entering the main stream, follow it up a short distance, taking a few samples. This prospection would show at what places camps should be located so the streams could be prospected more in detail. Fourth, follow up the streams running into the main stream, taking samples at different points. Follow them to their very head if they prove at all promising, as float indicating the presence of a vein may be found, of which samples should be taken. It is unnecessary to survey any small stream unless it proves promising, which can be done later when the stream is prospected more in detail. This can be done without loss of labor. It is not necessary to know anything of an unpromising stream other than to show on the map where it enters the main stream. A large stream entering the main stream should be surveyed in order to indicate promising and unpromising small streams entering it. Fifth, select the best of these small streams with an idea of finding if any of them would pay to exploit. A few samples would in-

dicate if any were poor, rich, or doubtful. Further sampling should be confined to the best ground, for if the best is not payable it would be a waste of labor to sample the poorer.

Sampling should not be carried any further than to enable comparisons to be drawn. For example, in the N'Gayn-Nepoka region sampling should not be carried any further than to make a comparison with Babeyen; if Babeyen is unpayable, it would be a waste of labor to do much sampling on streams that don't compare with it. Any extensive sampling of streams poorer than Babeyen must be suspended until Babeyen is shown to be payable. In most of the streams a very few holes is sufficient to draw a comparison with Babeyen, as they are decidedly poorer. As the value of the ground approaches that of Babeyen more holes are necessary. If decidedly richer a few holes is sufficient. In the first preliminaries (every prospection is more or less preliminary or more or less detail) where more or less of a qualitative test is desirable (every sampling is more or less qualitative, or more or less quantitative) it is sufficient to take a few pans off the bottom, selecting the most promising looking ground to sample, if that is possible. Such is often indicated by coarse gravel. Ground containing much other gravel than quartz may be passed with a few holes, if poor, for it is likely its pooriness is due to this gravel, which contributes nothing to the value of the gravel. Much heavy iron causes a great loss in saving the gold. Gravel with much iron may also be skipped with a few holes, if it is poor. Gravel of the large streams may be passed with a few holes, as the richer material is liable to be found in the branches. A hole is the best part of a stream, or what is considered the best part, and is all right where a qualitative test is all that is wanted. Small streams with little gravel can be passed with little sampling, on account of the great cost of working small deposits. If very rich, a few holes will show it.

It is admitted that by this method of prospecting there is a possibility of missing valuable ground; but in no sense is the sampling to be considered as final. There is always a chance, after the completion of this sifting process, of sampling the more promising of the unsampled streams until the expiration of the time allowed for prospecting. In other places where no time limit is set by law, the time is set by a prospector's pocket-book, and it is always desirable to find something payable as soon as possible. By a method that samples, alike, all streams as they are reached—a catch-all sort of a method—there is a greater chance of missing valuable ground than by the method mentioned above, on account of considerably more work having to be done by a few men in a large territory; there is also a chance of leaving unsampled a great amount of country at the expiration of the time limit. Prospection is essentially a process of elimination. The object in a preliminary prospection is not to find and sample every stream and ledge, but to find sufficient data to enable the company to make selections and to be able to outline the work of more detail prospection, so more prospectors can be put to work with the idea of

quickly finding the best. This same prospecting method—a process of elimination—can be applied to lode prospecting. I notice Mr. Charles H. White describes some such method in your issue of April 30.

Prescott, Arizona, May 10. WM. CROCKER.

The Mackenzie River Basin

The Editor:

Sir—Shortly after it originally was published, in the 'Mining and Scientific Press' of October 4, 1919, I reviewed Memoir 108, No. 92, Geological Series, entitled 'The Mackenzie River Basin', by Charles Camsell and Wyatt Malcolm. In the summer of last year oil was struck 45 miles below Fort Norman, and, as this official publication was the only one bearing on the district that had been issued by the Canadian Geological Survey, there was so great a demand for it that it soon became exhausted. The report has been revised; an account of the discovery by the Imperial Oil Co. is included, together with the result of a fractional distillation of the oil that has been made in the laboratory of the Mines Branch of the Department of Mines, at Ottawa, and the report is now available to those interested in the district.

A good deal of cold water has been thrown on the discovery by the technical press, particularly south of the international boundary, with a view, no doubt, of preventing a heedless rush of prospectors to the district, and also, to some extent, of counteracting the effervescence that a large part of the western Canadian daily press has exhibited. That a heedless rush of prospectors to this district would be little short of a calamity cannot be gainsaid, but, on the other hand, a careful perusal of the memoir under consideration can hardly leave the thoughtful reader with any doubt as to the great possibility, one might almost say probability, of the existence of an oil-field of considerable magnitude in this remote region. Let me quote: "It has been known for a century that oil seepages issue from the Devonian rocks of this area. It remained for the boring near Norman to demonstrate the occurrence of an oil-pool in these rocks. There is a vast area that may prove favorable prospecting ground. Rocks of the Devonian system are of wide distribution and stretch from near the mouth of the Mackenzie river south to beyond lake Athabaska (a distance of more than 1000 miles). They are overlain in places by rocks of Cretaceous and Tertiary age and pass beneath the Cretaceous sediments on Peace and Athabaska rivers. . . . In many places the Devonian strata are highly bituminous in character, and several petroleum springs are known. The upper beds penetrated by boring at Vermilion Chutes are impregnated with bitumen, and strata exposed near La Butte, on the Slave river, and in several places around the western arm of Great Slave lake are highly bituminous. Bitumen occurs in limestone at the Ramparts, in some of the dark argillaceous shales exposed at the water's edge along Grand View, and in the shales in a small plateau lying a short distance east of the Mackenzie, 15 miles below Grand View. The shales in this plateau are reddened in places by the com-

bustion of the bituminous matter. Fifteen miles farther down the river evenly-bedded, highly bituminous, black, Devonian shales occur". Of these R. G. McConnell says: "The laminae, when freshly separated, are moistened on the surface by an oily liquid, and burn when thrown into a fire. Patches of red shales, marking the sites of former fires, alternate with the dark varieties. The shales are exposed on the right bank for some miles, or almost as far as old Fort Good Hope". There is more in the same vein and other observers are quoted, but the foregoing is sufficient to show the character of the rocks for hundreds of miles within the neighborhood of the discovery. The possibility of finding a commercial oilfield in such a district would seem to be rosy.

The prospector, however, that contemplates visiting this district, and the investor that is prepared to stake him, must weigh other considerations besides the discovery of oil. First and foremost among the disadvantages is the inaccessibility of the district. Should a commercial oilfield be discovered it will take considerable time and an immense amount of money to construct transportation facilities whereby the oil may be brought to market. Neither the prospector nor the investor should delude himself with the idea, either, that it is possible to stake claims for speculative purposes while others, better backed financially, solve the transportation problems. The Dominion government has provided against such a contingency. It insists that an adequate drilling outfit must be placed on the property within two years of a permit being granted, drilling to a depth of 500 ft. must be done during the third year, and an aggregate depth of at least 2000 ft. during the fourth year, and in the event of non-fulfilment of these conditions the permit lapses automatically. Considerable pressure has been brought to bear on the Government to induce it to soften the harshness of these regulations, considering the inaccessibility of the region, and, while it is likely that they will be tempered to some extent, it is probable that they will remain sufficiently strict to bar the blanketing of the district with claims staked purely for speculative purposes. The transportation of a drilling outfit and supplies into this district is as difficult as the transportation of oil from it, consequently no one that is not well backed financially and that is not prepared to wait to receive the reward for labor and money expended should entertain prospecting for oil in the Mackenzie River basin. On the other hand, it seems to me that those that have weighed carefully these considerations and are willing to wait for their reward have as great an opportunity to succeed in the far North as in any other unproved field. The coming year will see a considerable amount of activity and a considerable amount of drilling in the district, and it is likely that within the next six months we shall know a great deal more about the possibilities than we do now. At the same time, of course, it will be the ones that go in now, always provided they are properly backed, that will reap the largest rewards, if rewards there be.

F. H. MASON.

ANTOFAGASTA, CHILE. THE PORT TOWN FOR CHUQUICAMATA

The Chuquicamata Enterprise—I

By A. W. Allen

Chile, perhaps the most progressive of South American nations, can boast the largest known copper deposit in the world, at Chuquicamata, in the Province of Antofagasta, in Lat. $22^{\circ}17'$ south, and Long. $68^{\circ}55'$ west. The port of Antofagasta was, previous to the War of the Pacific, 1879-1881, Bolivia's outlet to the sea. The overwhelming defeat of both Bolivia and Peru in that conflict resulted in a re-arrangement of a large portion of South America: Bolivia lost her seaport and was pushed back into the mountains; Peru lost the immensely valuable nitrate region that lies between the coast and the Andes, as well as the buffer provinces of Tacna and Arica. Chile became the paramount power on the west coast of South America.

The mining camp of Chuquicamata is reached by rail from Antofagasta by means of the Antofagasta & Bolivia railroad; the nearest station is at Calama, a small town about six miles from the copper deposit, and on the main line between the port and the city of La Paz, in Bolivia. The Chile Exploration company's property is situated near the main Pacific range of the Andes and at an elevation above sea-level of about 10,000 ft. So far as the atmosphere is concerned, the climate is delightful, although the variation in temperature is great; the principal drawbacks are the dust in and near the settlement, and the general aridity of the district. Rain is rare, but dews are heavy. Chuquicamata lies about 85 miles from

the Pacific, as the crow flies, 70 miles from the Bolivian border, and about 160 miles from Antofagasta.

As compared with the great majority of South American towns of the same size, Antofagasta pleases the foreigner by its cleanliness, its neatness, and its atmosphere of modernity. The streets are excellently paved, the inevitable plaza is well stocked and well kept, palms and sub-tropical flowers appearing in refreshing and pleasing contrast to the barrenness of the pampa that forms a background to the city, as viewed from the sea. There are delightful drives in the vicinity, a country club and several town clubs, and at least one hotel that offers comfort and cleanliness.

It is a day's journey from Antofagasta to Calama. The railroad was built by means of British capital, the shares being one of the most attractive and at the same time one of the most speculative investments on the London Stock Exchange. The original purpose of the road was to provide means for the transport of nitrate to the coast; in this connection its traffic figures are amazing. In spite of the fact that the gauge is only 30 inches, this railroad is supposed to hold the world's record for freight carried in proportion to its rolling-stock. However, a favorable factor is seen in the circumstance that there is an ample down-bill grade from the nitrate fields to the coast, so that most of the power is consumed in the haulage of empty flat cars and trucks from the port to

the pampa. In spite of the diminutive width of the road-bed, the Antofagasta & Bolivia railroad can boast of an excellent service of trains. The dining-cars are small but comfortable; and the meals served, considering the conditions, are good. Daily trains run between Antofagasta and La Paz, in Bolivia; and there are also two night trains every week. Comfortable sleeping accommodation is provided, but the booking of a *reservado* several days ahead is a wise precaution. The journey to Calama takes about 10 hours; the day train leaves Antofagasta at 8 o'clock every morning, arriving at Calama about 6 o'clock in the evening. The journey is entirely across the arid pampa of central Chile; the view from the open windows of the train is unrelieved by the sight of a single blade of grass or even an occasional tree; the country is bare of vegetation and devoid of water, for it seldom, or never, rains; and Darwin, observant naturalist though he was, could find nothing living except a small lichen that had grown on the bones of a dead mule! Nothing relieves the monotony except the sight of an occasional nitrate *oficina*, with its plant of crushers, boiling-vats, and *bateas*; or the sound of an explosion from a near-by *salitrera*, where the *caliche* is being mined and sorted, for transport to the loading station in carts, and from there to the *oficina* in the cars of a narrow-gauge railway. The last stage of the journey, between Calama and Chuquicamata, is made, through the courtesy of the Chile Exploration company, by automobile.

First impressions are often the most lasting, especially if pleasant. After a dusty and somewhat tiring train journey, the thoughts uppermost in one's mind are of home comforts; and these are precisely what the company has provided in the guest-house at the mine. Visitors are by no means uncommon. A number come from all parts of Chile to take advantage of the services and skill of a surgeon whose name is a household word in that part of South America, Dr. W. F. Shaw. Others travel there for business and professional reasons. Many make the journey for the purpose of viewing the greatest copper mine in the world, as I did. To one and all the guest-house at Chuqui, as the camp is called, is voted to be patterned along lines that many other mining concerns might well copy, for this sincere form of flattery is certainly deserved. The house itself is equipped according to American ideas of comfort and convenience; the cuisine equals that of the majority of first-class hotels; the guest is at his ease from the moment of arrival. One of the company officials lives in the house and acts as host, performing his duties with tact, and speaking Spanish or English according to the nationality of his guest. The sense of appreciation toward the company and its officials is brought down to a personal basis, for which visitors are glad to make due and fitting acknowledgment; a charge of 18 pesos per day relieves one, to some extent, from any uncomfortable feeling of pecuniary obligation toward the company. The entire arrangement ensures the comfort and pleasure of the guest, and might well be adopted by other industrial concerns operating under similar conditions.

The Chile Exploration Co. is essentially a Guggenheim enterprise, being controlled by the Chile Copper Co., which owns all the capital stock. The financial resources of the parent company are illustrated by the fact that it has a capital of \$135,000,000. The shares have a par value of \$25 each; 3,800,000 have been issued, and are listed on the New York and Boston stock exchanges; 600,000 are held for the conversion of 10- and 15-year gold bonds, aggregating \$50,000,000, which are due in 1923 and 1932, respectively. Extreme prices for the shares on the New York Stock Exchange during the past three years have been as follows:

	1920	1919	1918
High	21½	19½	24
Low	7½	16½	14½

Extreme prices for the bonds during the past three years have been as follows:

	Bond	1920	1919	1918
High {	7 %	108½	128	118½
	6 %	86½	95	89½
Low {	7 %	87½	101½	102½
	6 %	62	82½	77

It seems that Daniel Guggenheim, head of the firm of M. Guggenheim's Sons, first heard of the Chuquicamata mine in 1900. The firm turned the proposition down; but it must be understood that this step indicated no faulty judgment on their part; the only mines in which they were interested at that time were those containing ores that could be smelted, the leaching of low-grade material on a commercial scale being then unheard of. In 1911, correspondence took place between the Guggenheims and A. C. Burrage, of Boston; the property was shown to consist of a large number of claims that were owned by several syndicates and individuals, both Chilean and foreign. Between 1910 and 1911 a number of options were secured by Burrage; these were afterward taken over by the Guggenheims. A company was incorporated in New Jersey early in 1912, with a capital of \$1,000,000, in \$100 shares, the entire stock being held by the Chile Copper Co. The financial negotiations have not escaped litigation. In 1913, Louis Ross brought suit against Burrage in an endeavor to obtain 10% of the profit secured by the latter in the flotation of the company. Ross maintained that he was the original discoverer and that he had obtained the options for Burrage, working under a salary and a written agreement as regards commissions. After prolonged litigation, both suits were decided in favor of Burrage, the first by a decision of a lower court, from which Ross took no appeal, and the second by opinions of the Massachusetts Supreme Court in 1919 (233 Mass. 439, 124 N.E. 267) and on March 7, 1921 (130 N.E. 80). In 1916, the firm of M. Guggenheim's Sons was succeeded by Guggenheim Brothers. The change was one of the results of a suit that was brought by William Guggenheim against his brothers because of alleged unfairness in the division of profits arising out of the Chuquicamata flotation.

Chuquicamata marks the site of one of the ancient mines of the Indians, of which there are a vast number

in Chile. Old workings are numerous in the vicinity, and mummies are encountered from time to time as the work of stripping proceeds. The product from Chuquicamata, unlike that of the sister American enterprise (Cerro de Pasco) in Peru, was always copper, and was doubtless extracted by the natives for the making of ornaments. The mining area at present consists of 302 claims, and covers 2080 acres. Development work commenced in 1912, Pope Yeatman being consulting engineer. Sixty-three prospect holes were put down, totaling 44,185 ft. The average depth of the holes was 701.3 ft. The deposit was in this way determined to be composed of three classes of ore; the thickness of the ore was proved to be as follows: oxidized, 351 ft.; mixed, 228 ft.; and sulphide, 335 ft. The deepest hole disclosed ore of good grade at a depth of 1685 ft. Some trouble was experienced with acid water, but not on account of the action on the bits. The wire ropes used in connection with deep drilling were corroded, and delays resulted, but most of the drilling was done with manila rope. The depth to which the drilling was carried offers no evidence as to the depth of the deposit; many of the holes were in good ore when drilling was discontinued. It was noted, however, that the copper, in the sulphide zone, is occluded, and does not occur in the fissures and cracks; the treatment of this particular ore will, therefore, probably involve fine grinding; a concentrating, and not a leaching, process is certainly indicated.

The geology of the Chuquicamata deposit has been described at length by Waldemar Lindgren, Professor of Geology in the Massachusetts Institute of Technology; also by Fred Hellmann, Pope Yeatman, and others. The following notes, kindly supplied by the technical staff of the company, indicate the important features:

The country-rock in and about Chuquicamata is granite. It has sometimes been erroneously called granodiorite, but it consists essentially of feldspar, hornblende, and biotite, with sparse quartz inclusions. The orebody comprises a shear-zone within this granite area, which has been mineralized by solutions probably coming from great depth and connected with the basic intrusions that may be noted in the neighborhood. The mineralizing solutions have deposited the primary ore-minerals, enargite and cupriferous pyrite, in the fissures and on the joint-planes within the shear-zone. The deposited material did not impregnate the rock itself. This fact is of economic importance, because it enables the acid used in the lixiviation of the ore to reach the copper and to dissolve it with little difficulty, thus avoiding the necessity of fine grinding, as well as the added expense and the liberation of impurities contained within the country-rock. As it is, the ore is singularly free from impurities; the mineral occurs in such a way as to permit of the ready and rapid extraction of the copper.

Subsequently, erosion, oxidation, and metamorphism of this original orebody produced the rich area, consisting essentially of brochantite and chalcocite, out of the original ore-minerals, which were enargite and cuprifer-

ous pyrite. It is believed that this oxidation occurred at a time when the rainfall was abundant, or, at all events, was much greater than it is at present, and when, as a result of this rainfall, there was much water in circulation on the surface of the ground and at moderate depth. The upper portion of the deposit was undoubtedly leached at that time; its copper contents were carried downward by the descending waters, and re-precipitated on the primary minerals below, thus forming a secondary enrichment composed of chalcocite. It is likely that this period of enrichment was followed by a considerable amount of erosion, for the upper cap was swept away and the enriched mineral was exposed. With decreasing rainfall and greatly diminishing circulation, the exposed chalcocite was gradually changed into brochantite, to a depth of about 350 feet.

It would appear that at a later period the orebody underwent a further alteration, due to the deposition on its surface of sulphates of lime and soda, and also of ordinary salt. These sulphates appear to have penetrated to a moderate depth and to have reacted in some measure on the existing minerals, turning the brochantite into ordinary bluestone of commerce (chalcantite) and combining as well to form a mineral known as kronkite, which is a mixture of sulphate of soda and sulphate of copper. These phenomena are mentioned in order to explain the many peculiarities of chemical composition and pseudomorphism that are in evidence, and that attract much attention; they are the result of the above-mentioned processes. The characteristics of the orebody today are, first, that in its upper levels it consists of a sub-sulphate of copper called brochantite, which is a mixture of the ordinary sulphate of copper with cuprous oxide. Then in the next zone, of a mixture of the oxidized ore and of the sulphide, chalcocite; then at a still lower horizon, of chalcocite alone; and lastly, of the original primary material, enargite and cupriferous pyrite.

The orebody as found today is an elongated mass, the direction of the long axis of which is approximately north and south. It is about 9000 ft. long, and has been proved for a maximum width of about 1300 ft. Its depth is as yet unknown, but the company's bore-holes show that it has a thickness of at least 914 ft. Assuming the depth attained and not going beyond it, and restricting the calculations to the area within the bore-holes themselves, the ore-reserves developed to date and in sight amount to 700,000,000 tons of an average content in copper of 2.12%.

By January 1913, 75,000,000 tons of ore, averaging 2.7% of copper, had been assured. By July 1913, the amount had been increased to 146,000,000 tons of 2.31% ore; and by January 1914 the reserves were estimated at over 200,000,000 tons, containing over 2% of copper. During 1914 an extra 100,000,000 tons was added to the reserves; and, during 1915 and 1916, 400,000,000 tons more. The graphic representation of drill-hole data was made by means of the pegboard method, which is de-

scribed by E. A. Cappelin Smith* as follows: A table was used to represent the datum plane, which would lie, in the case of the Chuquicamata deposit, about 1200 ft. below the surface of the earth. On the surface of the table a projection of the claim lines, as well as topographical features of importance, were laid out. The pegs used consisted of brass rods, cut so that their height represented the elevation of the surface at the various points; the tops of the rods, therefore, gave the surface contour of the deposit. Paper strips were graduated to represent intervals of 5 ft., with heavier divisions at intervals of 25 and 50 ft. These strips were wrapped around the brass rods, and glass tubes were slipped over them. Any legend on the paper remained clean; it was easily marked. The paper scales were painted in different colors at the various depths, to represent cap, brochantite, mixed brochantite and sulphide (one way if the former predominated, another way if the latter predominated), straight sulphide, and country-rock. The scales also bore little squares on which the copper assays at various depths were entered. Consequently, on looking across the pegs, a geological section of the deposit, in colors, could be seen, so far as drilling had determined it; and, by closer inspection, the depths and assays could be ascertained for any particular point. When further results on any drill-hole were received, the paper was taken off the peg, appropriately colored, marked to the new depth, and returned to its place.

Leaching tests were commenced in 1912 on a small scale. Composite and selected samples were taken from various sections of the deposits. The amounts experimented with were gradually increased from 100 kilogrammes to 2000 kg. and, lastly, to 14,000 kg. The success of subsequent operations was due largely to the completeness of the preliminary investigations, the final tests being made on a depth of ore equalling the height of the vat that was afterward used in practice. The solubility of the copper minerals was determined, and extensive experiments were made in an effort to anticipate the conditions that would be encountered in practice. An acid-proof material for lining the vats was developed and perfected, and much attention was paid to the question of the composition of a suitable alloy to be used for anode construction. The final decision was that a unit of 10,000 tons daily capacity should be erected, in which the ore would be crushed to about half an inch, and then leached with weak sulphuric acid; the solution would be dechloridized by treatment with metallic copper, and the copper would be recovered by electrolytic deposition.

Concurrently, the question of an adequate supply of power was receiving consideration. The company had obtained a concession for a water-power site from which it would be possible to obtain about 20,000 hp.; but, in order to economize time, labor, and first cost, and because this amount would be insufficient for the demands of even the first unit, it was decided to erect a steam-power plant at the coast, and to carry the power by overhead high-

tension lines to the mine. The available water-power will doubtless be utilized at a later date. The power-plant is situated at Tocopilla, a small seaport about 80 miles north of Antofagasta. Tocopilla was noted during the latter half of the 19th century as a copper centre of no small importance. Up to 1885, a number of large mines and smelters were in operation, all of them being under British control; the cessation of operations has been attributed to a combination of mismanagement and faulty technique. Today the town possesses one of the largest and most up-to-date steam-power electric plants in South America. The steam required for the original equipment was obtained from sixteen 2500-kw. Babcock & Wilcox tubular boilers. The fuel used is Californian oil, for which there is storage for 165,000 bbl.; economizers and steam-superheaters form a part of the equipment. The steam goes to four turbines of Swiss design constructed by the Escher-Wyss Co., of Zurich. The generators, of which there were also four, were made by the Siemens-Schuckertwerke, the current produced being of the three-phase 50-cycle alternating type at 5000 volts. The voltage is raised, in four Siemens-Schuckert 10,000-kva. transformers, and one 20,000-kva. General Electric transformer, to 110,000 volts. The overhead transmission line to the mine, 140 kilometres long, is carried on galvanized-steel towers, which are spaced according to the topography. The transmission consists of three 7-strand cables of 000 gauge (Browne & Sharpe) copper wire; ground wires are carried above the power cables. The insulators are of a tested capacity of 250,000 volts. At Chuquicamata the high-tension current goes to substation A, where four 10,000-kva. transformers and one 7500-kva. Westinghouse transformer reduce the pressure to 5000 volts. A portion passes to seven motor-generator sets and four rotary converters, a portion to substation B, where three 1000-kva. transformers reduce the current to 525 volts, at which pressure all the alternating-current motors on the property are operated. The current used for the electrolysis of the copper solution from the vats is of 250 volts.

Construction of the new plant began in January 1913. Orders for much of the electrical machinery had been placed in Germany; all went well until the outbreak of the War, when it was realized that a dozen or more English and German ships on the high seas were laden with equipment that was essential to the success of the Chuquicamata enterprise. An agreement was reached with the Allies; the machinery was transferred to neutral bottoms, and ultimately delivered at the mine. The Allies, in return, secured a quantity of copper when the plant was in operation. 'It's an ill wind that blows nobody any good'. The War helped the Chile Exploration Co. to a considerable extent. The nitrate fields had been producing at excess capacity to meet Germany's enormous pre-war demands for fertilizer. Then disorganization occurred. Ocean traffic was impeded, and Germany made an effort to keep a lane open between the Chilean pampa and the Fatherland; von Spee, the German admiral, terrorized the West Coast of South

*E. & M. J., May 16, 1914.

America; the nitrate industry was paralyzed. The complete destruction of Admiral Cradock's squadron off the Chilean coast on November 1, 1914, was an example of superior strategy and superior armament; it marked the extinction of the sentiment, upheld by Cradock, that boldness, morale, and valor, would decide the day. The Germans were flushed with victory; their fleet put into Valparaiso and, foolishly for them, took aboard a number of reservists. An Englishman put two and two together; he surmised that the fleet would double the Horn and make a dash for home. He cabled his views to London. The supposition seemed feasible. Fisher sent a squadron headed by the battle-cruisers 'Invincible' and 'Inflexible' under the command of Sturdee. The Germans were caught off the Falkland Islands on December 8 and were annihilated.

Owing to the restriction of output from the nitrate

man and other associates, the presentation was significant as recognizing the outstanding feature of really successful hydro-metallurgical work of recent date, namely, the enormous economic importance of gravity-leaching in the treatment of ores containing metals or salts in soluble form. The preliminary work, which was carried out to a large extent in the United States, anticipated to an unusual degree the results of operation on a large scale. A simple scheme of treatment was selected. The plan, as at first devised, was to crush in No. 10 gyratory crushers; but the opening was found to be too small; primary rock-breakers had to be installed later. Garfield rolls were chosen for final reduction to $\frac{1}{2}$ inch, but disc-crushers were found later to be preferable. The essential features of the disc-crusher cannot well be over-emphasized. The material is fed centrally between the discs, and is thrown by centrifugal force toward the periphery, where it is

THE POWER-PLANT AT TOCOPILLA

fields, the Chile Exploration company was able to engage labor on a large scale. Progress in the erection of the plant was rapid, the first unit being completed on May 15, 1915, little more than two years after the starting of the work. The high price of copper provided a big incentive for haste. It was estimated that copper could be produced for six cents per pound, delivered in the United States or in Europe. The mining and treatment cost per ton was anticipated to be \$2.106.

It speaks well for the technical organization of the enterprise that, comparatively speaking, so few alterations were made in the original design of the plant. The success of the metallurgical side of the operations is associated to a great extent with the name of E. A. Cappelin Smith, to whom the Mining and Metallurgical Society of America awarded its gold medal in 1920 for "distinguished service in the art of hydro-metallurgy". Although the honor was modestly disclaimed by the recipient, who emphasized the great services of Pope Yeat-

crushed; the discharge takes place in the same direction, and is aided by the centrifugal action; the ore travels in the direction of an increasing area of discharge, thus obviating the lowering of efficiency and minimizing the fine crushing of ore on ore that occurs in rolls. Leaching could also have been carried out on a deeper bed of material. The shoveling-slats in the leaching-vats were laid at right angles to the direction of operation of the grab-buckets, instead of in line with it. A 1000-ft. belt-conveyor was erected for the disposal of residue, to be super-seded later by cars and locomotives. The copper solution before going to the electrolytic vats was de-chloridized by passage through tube-mills containing shot-copper, the idea being to settle, in Dorr thickeners, the cuprous chloride formed, and to filter the sludge, preparatory to smelting, in presses. The de-chloridizing process has been modified, as will be described later. The Dorr thickeners are now operated as gravity settlers and without the use of the customary mechanism; the tube-mills are filled

with scrap-iron instead of copper, and the necessity for the filter-presses no longer exists. The anodes in the electrolytic department were to be made from magnetite. These were purchased in Europe, but the War soon cut off the supply. Duriron, which had been tried as an anode material in the Perth Amboy tests, was substituted for magnetite, although a considerable increase (about 13%) in power consumption resulted. The anodes are now cast at the mine from ferro-silicon that is made in an electric furnace. The acid-plant is in excess of present requirements, although it will probably be an asset when extensions of plant are made. The ore was found to contain a large proportion of the acid required for dissolving purposes.

Errors of judgment in the preliminary planning of so vast an undertaking have been few and far between. It is refreshing to leave the piles of scrapped 'up-to-date' machinery at the more 'progressive' nitrate *oficinas* and to reach Chuquicamata, where practice has been based on sound fundamental principles of metallurgy and economics, rather than on the dictation of reformers who are, too often, interested in the application of the machinery, the use of which they advocate.

(To be Continued)

Aluminum

*Aluminum is the lightest of the common metals, and has a specific gravity 2.58 in the pure cast condition. The metal is malleable between 100° and 150°C. It can be forged and rolled, drawn into tubes and fine wire, stamped, pressed, and beaten into thin leaves. Assuming an electrical conductivity of 100 for pure copper, aluminum has a conductivity of about 60. Commercial aluminum usually contains from 98 to 99% of the metal, but ingots can be obtained containing only 0.3 to 0.5% of impurities. The most objectionable impurity is sodium, of which not more than traces should be present. Other impurities include silicon, which should not exceed 0.5%, and iron, which should not exceed 0.3% in high-grade aluminum.

The chief aluminum minerals are corundum (alumina), bauxite, hydrargillite* and diaspore (hydrated oxides), cryolite (a fluoride of aluminum and sodium), alum, alunogen, and alunite (sulphates) and numerous silicates, including the feldspars and clays. Cryolite is found in commercial quantities only in southern Greenland, where it is mined at Ivigtut, on the Araukfjord. This mineral was formerly the only ore of aluminum and it is still used as a flux in the extraction of the metal. It is also used in enameling iron-ware and in the manufacture of portland cement.

The Ivigtut deposits are owned by Kryolith Mine and Handelsselskabet, A/S, Copenhagen, Denmark, which holds a State concession for mining. The product is sold to the Pennsylvania Salt Manufacturing Co. of

Philadelphia, and to Oresunds Chemiske Fabriker, Kommanditselskab ved C. F. Jarl, Copenhagen. Canada obtains its supplies through the American agents.

Bauxite is the most important source of aluminum and its salts. It is a mixture of the hydrates of aluminum and iron, with a certain amount of silica, silicates, and titanium oxide. Its color varies from gray to red, according to the percentage of iron. Its composition ranges generally between the following limits:

Alumina	30	to 60 %
Ferric oxide	3	" 25 "
Silica	0.5	" 20 "
Titanium di-oxide	0	" 10 "

Bauxite is employed (1) as raw material in the production of metallic aluminum, (2) in the manufacture of aluminum salts, (3) in the manufacture of refractory bricks, (4) in the manufacture of alundum (fused alumina) for use as an abrasive, and (5) in the refining of oil, a use of growing importance.

The greater part of the world's output is employed in the production of metallic aluminum. For this purpose the percentage of silica and titanium oxide should be as low as possible, but a certain amount of iron-oxide is not injurious except so far as its presence means a decrease in the alumina content. In the manufacture of chemicals such as alum, aluminum sulphate, and other salts, comparatively pure bauxite is used, and it is desirable that the material should be as free as possible from oxide of iron. For some purposes, practically pure hydrated alumina must first be obtained.

Large quantities of light alloys of aluminum, with copper alone, or with that and other metals, such as magnesium, have been used for war purposes, chiefly in the manufacture of aeroplanes and airships, but also in machine-guns of the air-cooled type, in the manufacture of ammonal and other explosives, in soldiers' helmets, and other parts of their equipment. Other uses include wireless telegraph and telephone apparatus, barometer cases, and camera parts. The use of aluminum dust in place of zinc-dust for precipitating precious metal from cyanide solutions is increasing. Aluminum is also largely used in the Thermit process of welding and casting, aluminum in fine grains or filings being mixed with the oxide to be reduced. On being heated by a priming, such as magnesium powder, the aluminum combines violently with the oxygen, generating great heat, producing a fluid slag, and setting free the metal, thus proving useful in the welding of steel rails.

The Central Powers were seriously short of supplies of bauxite during the War, and the urgency of their need led to attempts to extract the metal from clays. In Norway it has been proposed to extract aluminum from the feldspar labradorite.

All the bauxite produced in the United Kingdom comes from Ireland. It occurs associated with the pisolitic iron ores and laterites of Antrim, in the area lying north and north-east of Lough Neagh, between Belfast Lough and the north coast of the county.

*Abstracted from a pamphlet issued by the Imperial Resources Bureau, London.

Underground Haulage for Mines of Moderate Size

By Girard B. Rosenblatt

*The selection of the most suitable system of haulage for the metal mine of moderate output—say 500 to 2000 tons of ore per 24 hours—deserves more careful consideration than is generally accorded to it. The advantages of mechanical haulage are generally recognized, but a cost analysis of the various systems available is not generally made before deciding upon the type that will be installed. First cost is frequently given more or less careful consideration, but factors affecting the cost of operation are often overlooked. It is the purpose of this paper to discuss some aspects of the problem that should be considered in determining what system can be installed most advantageously.

This is not a brief for electric haulage, but I believe it will be admitted that on account of the flexibility, reliability, and comparative simplicity of electric locomotives, this form of mechanical haulage will prove most applicable in the majority of mines. Gasoline locomotives and compressed-air locomotives have their particular fields of application, but these fields are limited. The proper field of the gasoline locomotive is to haul small tonnages over comparatively long distances on temporary work under conditions where it is more important to keep low the total initial investment than to secure continuity of service or economy of operation and maintenance. The particular field of the compressed-air locomotive is to transport large tonnages over long hauls where conditions necessitate heavy trains, but where the physical surroundings prohibit the installation of a trolley or third rail. For all other conditions electric haulage can be proved to be superior.

When we come to a consideration of electric haulage we are immediately confronted with the necessity of choosing between two distinct systems of power-supply, namely, trolley or storage-battery. A decision having been made on that point, it next becomes necessary to select the unit of proper size. And that point being settled, there finally comes the selection of the desired equipment from among the products of the different manufacturers. This paper will not treat of the advantages and failings of equipment made by different manufacturers, nor will it cover the method of calculating the proper size of haulage-units to be used. But it will endeavor to point out the advantages and limitations of the systems that can be selected and certain considerations that should be borne in mind in arriving at the most desirable type and size of equipment.

In selecting haulage equipment, the primary thought to bear in mind is that mechanical haulage is to be installed in order to help the mine make money. It makes

money by saving expense. The type, size, and make of equipment that will handle a given output with the least expense is the logical type to install. Do not select your haulage system on the basis of lowest first cost alone; nor on the basis of some individual's preference. First cost and personal preference are factors entering into the problem, but they are not the only, nor even the predominating, factors to be considered. Select your haulage as engineers should; that is, on the basis of a complete logical analysis. And the foundation of such analysis should be *cost per ton of ore hauled*.

The principal factors that enter into the cost per ton of ore hauled are:

- Reliability.
- Operating labor expense.
- Maintenance expense.
- First cost of the complete installation.
- Safety.
- Flexibility.
- Personal preferences.
- Power consumption.

Upon the reliability of its component parts depends the continuity of service that the haulage system will render. Interruptions mean money lost. Delays in continuous service are expensive. A locomotive out of service for repairs, a train held up on account of a trolley-wire down, mean money going out and none coming in. Not only is there involved the expense of putting the locomotive back in service or of stringing up new wire; in addition interest charges are going on; ore is piling up in the chutes; perhaps even the output of the mill is being reduced. Select your haulage equipment so that, for your particular conditions, time-out-of-service will be a minimum. To do so will reduce your costs per ton hauled by keeping up the tonnage for a given investment.

Upon the selection of the proper size of locomotives will depend largely the operating labor expense. Every locomotive must have a motorman. In many States every train must have a trip-rider as well. Locomotives smaller than necessary mean more trains for a given output and consequently more wages per ton hauled. Make your trains long enough to keep the number of locomotives required down to a minimum, but of such size as to keep those locomotives busy. Locomotives standing idle and motormen loafing, run up the cost per ton of ore. Train-length up to a certain limit spells economy, but above that limit, too long a train means unnecessary expense, for very long trains are more subject to derailment than short ones; they cause confusion at stations; and offer some difficulties when loading from chutes. Wider gauges and heavier rails permit longer trains. There is an economical length, depending largely on the design

*A paper presented before the San Francisco Section of the A. I. M. & M. E., on April 22, 1921.

of car and the tonnage to be hauled. For the average small mine it is usually somewhere between 12 and 20 cars. The maximum weight of locomotive that can be used depends upon the gauge and weight of rail used. Often it will pay to use a wider gauge or a heavier rail than at first contemplated, in order to use heavier locomotives so as to haul longer trains and reduce the number of locomotives required for a given rate of output.

The accompanying table shows the allowable limits of the weight of locomotives to be used on rails of various weights and tracks of different gauge:

Weight of rail, lb.	Gauge of track, in.	Weight of locomotive, tons
12	18	4
16	20	6
20	24	8
25	26	10
40	30	15
..	36	20

Under 'maintenance expense' the upkeep of the haulage system as a whole should be considered. The upkeep of the overhead trolley-wire on a trolley-operated system should be included in considering the maintenance of a trolley-locomotive just as upkeep of the storage-battery is almost invariably included in figuring the maintenance of a battery-locomotive. In fact, for a fair comparison of real costs on a ton-mile basis there should be included:

- Locomotive maintenance.
- Car maintenance.
- Track maintenance.
- Battery maintenance, if any.
- Trolley maintenance, if any.
- Motor-generator maintenance.

First cost should include consideration not only of the cost of locomotives and cars, but also of such factors as the cost of motpr-generator or charging-stations, the stringing of trolley-wires, and the bonding of rails. The manner in which first cost enters into total operating cost is simply a matter of bookkeeping and will not be discussed here.

As to safety, all systems of haulage involve a certain accident hazard. The reduction of this hazard should receive major consideration. Apart from the humanitarian side of the problem, accidents are bad business. They are costly and they tend to reduce operating morale. A safe system goes far toward reducing the cost of haulage. The possibility of danger from electric shock is usually the feature particularly in mind in considering the accident hazard of electric-haulage systems. But there are others that should not be overlooked. They involve control and braking of the train, and protection

for the motorman in case of collision. I believe that fully as many train-operators are hurt in mining service by runaways and collisions as are injured by electric shock.

The value of flexibility in a haulage system is difficult to estimate. Yet it is quite real. Haulage systems can readily have a life of ten years or more. Few mines, especially lode mines, are operated on the same basis of development over ten-year periods. Physical conditions change, managements change, engineering ideas change, and metallurgical processes advance. A haulage system that may be ideal for present conditions may be a handicap ten years, or even two years hence, unless that system has a certain flexibility which will permit it being adapted to probable changed conditions. This aspect is worth thinking about.

Personal preferences enter into the problem of selecting haulage equipment on account of the personal element. Haulage equipment cannot be made strictly 'fool-

4 1/2-TON STORAGE-BATTERY LOCOMOTIVE IN THE HECLA MINE AT BURKE, IDAHO

proof' and operators usually get better results with equipment they like than with that they do not like. Features that render inspection easy, and that facilitate adjustments and lubrication, tend to lessen maintenance expense. A machine that is easy to oil is almost sure to get more frequent and more adequate oiling than one which is so constructed that periodic oiling becomes disagreeable and troublesome. Men will keep an easily adjustable machine in good adjustment, and will not so readily allow it to get in such bad adjustment that it must be withdrawn from service for repair in the shop.

Power consumption enters into the cost of mine-haulage to a less extent than is usually realized. It is seldom of sufficient importance to govern the selection of the

particular system of haulage. In half a dozen mines regarding which I have reasonably accurate haulage-cost data, power constitutes only about 5 to 6% of the total haulage-operating cost. Ordinarily 10 kw-hr. will haul approximately 75 tons of ore per mile on level track under average mine conditions. At the usual figure at which a mine buys power, it can readily be seen that a variation of 10% in power consumption will not make a very great difference in the total cost per ton of ore hauled. Efficiency of the electrical equipment on the other hand is a matter of considerable importance, but not so much because of power consumption as because of the effect of efficiencies on securing a well proportioned haulage system. To explain: Suppose as a hypothetical case we have a small system operated by a

trolley during a busy shift, or that an extra trip on overtime was necessitated in order to get out the requisite tonnage of ore, would increase haulage costs appreciably.

As a matter of fact, for average mining conditions the two systems—trolley and storage-battery—usually will not show a great difference in over-all power consumption. I know this is contrary to general impressions, but I have found it to be the fact in scores of instances that I have analyzed.

A consideration of the foregoing factors will aid in the selection of the most economical haulage system for any specific condition. No general rule can be laid down as to when trolley haulage or when storage-battery haulage can be installed to best advantage. Each problem must be investigated separately. However, a few

8-TON TROLLEY-LOCOMOTIVE AT THE ALASKA TREADWELL MINE

single storage-battery locomotive. A storage-battery locomotive carries its own power supply with it—on its back. Suppose the capacity of the battery is such that, with equipment having an efficiency of 70%, it is capable of hauling 100 tons of ore 10,000 ft. in five trips of 20 tons per train. If the electrical equipment had an efficiency of, say, 60 instead of 70%, this same battery capacity could make only $6/7$ the number of trips, or $4\frac{1}{2}$ trips. As fractional trips are impracticable, this reduction of 10% in the efficiency of the electrical equipment entails the necessity of re-charging the battery at the end of four trips, or of shortening the train hauled so that only 17 instead of 20 tons would be hauled each trip, giving an output of 85 instead of 100 tons in five trips. The fact that the inefficient equipment took 10% more power would not increase mining costs materially; but the fact that time was required to re-charge the bat-

generally applicable remarks indicating the trend of recent engineering experience may be of value.

As a simple, rugged, reliable piece of haulage equipment, the trolley-locomotive surpasses any other form of haulage motive power. As a means of moving trains quickly, irrespective of tonnage or distance, its superiority is unquestioned. The trolley-locomotive can be built for any speed that a mine track will stand. It can be subjected to almost unbelievable abuse, both mechanically and electrically; it can be plugged, derailed, 'slam-banged' into trains of cars, and yet stand up to the service with minimum deterioration. It is handicapped by just one feature, and that is that it requires a trolley-wire in order to be able to move about. Trolley-wires may be a menace to safety and interfere with flexibility. In heavy or moving ground and about loading-chutes it may be a decided nuisance and require con-

stant attention. Also, trolley-wire and rail-bonds cost money to install and money to keep in condition.

The modern storage-battery mine-locomotive is not the delicate piece of apparatus its detractors claim it to be; in fact it is a mighty good mining machine, but it will not stand the abuse that a trolley-locomotive can withstand. Operated with reasonable intelligence and given decent maintenance it will perform most satisfactorily in mine service. But it does require in certain particulars, greater intelligence in its operation and greater care than does a trolley-locomotive.

The actual mining conditions usually decide whether trolley or storage-battery haulage is the better to install. For large tonnages over long hauls, the trolley system will almost universally prove most advantageous. For many frequent and diversified short hauls with moderate or small tonnages—gathering service as it is termed—storage-battery haulage will probably prove more suitable. For small tonnages over moderately long hauls, storage-battery haulage will generally prove more economical, particularly since the investment and maintenance charge of the trolley-wire and rail-bonding for a trolley system would necessarily be divided among a comparatively few tons of ore hauled.

Long straight adits in which high haulage-speed is permissible and desirable will always favor trolley-haulage. Poor roof conditions, on the other hand, cause storage-battery locomotives to appear most favorable, because a bad roof means trouble in keeping up the trolley-wire; and a trolley-wire down is not only a nuisance and expense, but it means a haulage system tied up until the electricians are sent for and arrive on the scene to clear up the trouble.

A mining system that involves constant advance of haulage-drifts favors storage-battery haulage, because the storage-battery locomotive can follow development as soon as rails are laid, whereas the trolley-locomotive has to wait for the stringing of trolley-wire with the attendant barring-down of the roof and re-alignment of the timbering.

Low roofs favor storage-battery locomotives as a matter of safety. Certain methods of stoping also are favorable to storage-battery locomotives in haulage-drifts because many forms of chutes prohibit a trolley-wire strung over the centre of the track, and such chutes, unless all are situated on the same side of the track, make trolley operation difficult.

Altogether trolley-haulage makes for speed and big output. Storage-battery haulage makes for convenience and flexibility. The variety in types of storage-battery locomotives that comparatively recently have been placed on the market emphasizes the flexibility that can be attained with this form of haulage. Two or three manufacturers now sell a small narrow-gauge single-motor storage-battery locomotive that is particularly suitable for development work. This is a small light machine weighing about 2½ tons and available for gauges down to 18 in. It has limited pulling-power and a limited range of travel, but it will go almost anywhere and can displace three or four mules at a decided saving in cost of operation. At least two manufacturers now make a 'midget' locomotive—a small tandem affair built in two halves; the leading half carries the motor and the motor-man, while the trailing half carries the battery. Each half is of such dimensions that it can be run onto the ordinary mine-cage just like a mine-car. It can thus be shifted from level to level with the greatest convenience. Coupled together the two halves constitute a decidedly respectable haulage-unit that will develop about 400 lb. drawbar pull at approximately 3½ miles per hour. The unit has short wheel-base so that it can take any reasonable curve. It is less than four feet high, so that it can go into low drifts and snake cars from any place where rails are laid. To date it marks the ultimate in all-round flexibility.

The figures in the accompanying table analyze the cost of transportation at various mines in the United States and Canada during the years 1916, 1917, and 1918. These data show how the various factors enter into the total cost of moving ore. They have been obtained by carefully calculating to a ton-mile basis the costs as prepared by the mining companies themselves. The comparatively small importance of the item of power is notable in contrast to the large cost for operating labor and maintenance.

ZINC forms the base, according to a U. S. Geological Survey bulletin, of four white pigments: zinc oxide, leaded zinc oxide, zinc-lead oxide, and lithopone. All these may be, and in the United States the first three usually have been, made directly from zinc ore. No zinc-lead oxide has been made since 1909, when the plant at Cañon City, Colorado, was closed. The output of zinc oxide and leaded-zinc oxide has not been disclosed.

Table Showing Costs of Haulage in Cents per Ton-Mile of Ore Hauled

	Storage-battery 3-ton	Storage-battery 4-ton	Storage-battery 3-ton	Trolley 3-ton	Storage-battery 3½-ton	Storage-battery 6½-ton	Trolley 3½-ton

REVIEW OF MINING

COPPER PRODUCTION DURING APRIL

The closing down of most of the large copper mines has resulted in a comparatively small number of companies reporting production results for April. To date but eleven copper companies have made known their April production; of these 50% are now closed down so far as production is concerned. May, therefore, will be an extremely lean month. The eleven companies that have announced their April production figures show a combined production of 127,578.355 lb. for the first four months of this year, a drop of 31,711,930 lb., as compared with the corresponding period of 1920, and a decrease of 21,278,354 lb. from the first four months of 1919. The following compares the refined copper production by the eleven companies that have reported for the first four months of the last three years, the figures being in pounds:

	1921	1920	1919
Arizona	8,300,000	12,000,000	11,800,000
Calumet & Arizona.....	11,427,672	13,978,000	12,042,000
Cerro de Pasco.....	17,804,000	18,954,000	20,040,000
East Butte	5,164,580	6,400,760	5,973,320
Kennecott	25,138,500	34,322,660	24,712,000
Mohawk	4,228,268	4,190,203	4,736,823
New Cornelia	8,230,870	13,948,000	14,654,000
Old Dominion	7,887,000	9,146,300	10,135,000
Phelps Dodge	27,395,000	31,316,000	37,659,909
United Verde Extension...	12,013,990	13,902,600	5,284,508
Wolverine	1,388,409	1,131,762	1,819,149
Total	127,578,355	159,290,385	148,856,709

P. G. BECKETT, GENERAL MANAGER FOR THE PHELPS DODGE CORPORATION, IS OPTIMISTIC

That the crisis in the copper situation has passed and that the question now confronting the mining companies is the rapidity with which economic conditions in the country will return to normal, was the statement made by P. G. Beckett, general manager for the Phelps Dodge Corporation, at Tucson recently.

He is quoted as saying: "Conditions are naturally quiet now at many of the mining camps. Our branches at Tyrone, New Mexico, and at Morenci, are completely shut-down, and at Bisbee, the Copper Queen branch, we are doing considerable development work in the mines. We are also doing stripping work on Sacramento Hill and are completing construction of a 4000-ton concentration plant, which should be finished by fall, at the property of the Moctezuma Copper Co. at Nacozari, Mexico.

"We are also completing construction on a new concentrator and giving employment to several hundred men at the mines by doing certain development work. While it is difficult to appear in the role of a prophet at this time, I believe it safe to say that as conditions in this country and in Europe become better readjusted a gradual improvement will develop in the copper industry in this country. And while it is impossible to say just how long a time will elapse before the Phelps Dodge properties are justified in resuming production, the fact that practically all large copper producers of this country have completely suspended copper production will hasten the time.

"It is now generally recognized that with the overwhelming surplus of copper there was on hand in the spring of this year, the quickest way to a resumption of healthy conditions

in the mining industry in Arizona was a complete stoppage of copper production until a great part of the surplus could be absorbed. It may be said that the worst is over, and it is now a question of how quickly economic conditions here and abroad return to normal."

I. W. W. ORGANIZER IS SENT TO PRISON

A. S. Embree, one of the leaders of the I. W. W., who has been actively connected with strikes in various Western mining districts, has been convicted in the Superior Court at Wallace, Idaho, of criminal syndicalism, and sentenced to serve a term of from one to ten years. Embree admitted on the stand that he was a member of the I. W. W. and that for two months in 1918 he acted as supreme officer in Chicago during the absence of William D. Haywood.

Embree was active in the strike in the Warren district in Arizona in 1917, and was one of the executive committee that signed the I. W. W. demands. He was deported on July 12, 1917. He later returned and was arrested on a charge of inciting a riot, and was tried at Tucson, a change of venue having been taken, and was acquitted. He went to Phoenix, where he had charge of the I. W. W. headquarters, and later went to Butte, where he was active in the work of the organization there. Embree then went to Idaho and was arrested while circulating literature of the organization and making speeches in its behalf. His arrest occurred about six months ago. Embree was to have been tried last August but his case was postponed until the present term of court.

ARIZONA

Ajo.—Mining operations of the New Cornelia Copper Co. have been reduced to the minimum. The company could not shut-down entirely because of the damage to its plant and equipment. It has thousands of gallons of sulphuric acid and other leaching solutions in tanks at its reduction works which cannot well be disposed of and if allowed to lie idle would quickly deteriorate. The company will continue to run one steam-shovel on an eight-hour shift at its mine. This will entail the employment of approximately 300 men. The town of Ajo is completely dependent upon the operation of the mine, as is also the railroad connecting Ajo with Gila on the Southern Pacific line. Net working capital today is approximately the same as at the close of last year, namely, about \$4,750,000.

Bisbee.—No further reductions in wages in the district are contemplated, according to G. H. Dowell, general manager of the Copper Queen branch of the Phelps Dodge Corporation, who spoke before a meeting of business men of the district. Dowell spoke to put at rest rumors to the effect that there would be further cuts in the near future. The speaker said that the Copper Queen is now employing about 1300 men in the district, with a monthly payroll of \$180,000. The Calumet & Arizona, the second largest producer in the district, is employing about 600 men. Both companies are carrying on extensive development work during the period of the suspension of production.

Clifton.—Recent developments in the Volcano mine, situated seven miles from Steins, New Mexico, indicate that this

silver producer of 20 years ago may become important. C. W. Mitchell, mining engineer of Silver City, has recently found a rich vein, 12 ft. wide, on the 100-ft. level. Further development work is now being done.

Tombstone.—The mill of the Tombstone Co-operative Mining Co. is in regular operation on 7-oz. silver ore from Springer & Hilton lease. Assays of the concentrate, which represent from 75 to 80% recovery, average 373 oz., according to V. C. Mellgren, manager of the mill. The cyaniding equipment is being installed and all 'middlings' will be cyanided. There are eight independent lessees interested in the project and each lessee furnishes the labor required to put through his ore, which cuts the expenses to a minimum. Power is supplied by a gasoline engine. Once dumped into the bin all ore is automatically handled through the rolls into the feed-boxes and onto the tables, the flow being by gravity.

CALIFORNIA

Bodie.—Gold ore from the Miller, Gray, and Granger-Miller leases is being crushed. This is the first time the stamps have dropped for many years.

Grass Valley.—H. M. Black and associates, who are engaged in unwatering and repairing the shaft of the Iron-clad mine in the Rough and Ready district, have worked down a distance of 50 ft. The shaft is the deepest in the Rough and Ready district, being sunk to a depth of 400 ft. The old records show that excellent assays were secured at the point where work was suspended.

A meeting of mining men from various districts of upper California was held here last week. Among those attending were Bulkeley Wells of Denver, head of the Idaho-Maryland development, W. J. Loring of San Francisco, B. I. Hoxsie of Amador City, O. McCraney of Shawmut, F. O. Lincoln of Reno, and Alfred Hunt of Angels Camp. George W. Starr, J. A. Fulton, A. D. Foote, and Arthur B. Foote were among those who met the visitors and took them on tours of the different mines.

Nevada City.—The Quaker Hill Mines Co.'s property, 12 miles east of here, are to be sold at Commissioner's sale to satisfy a mortgage of \$150,000. This is according to a decision of Judge George L. Jones in the Superior Court. Judgment in the suit for foreclosure was given in favor of the plaintiff after the testimony had been heard. The plaintiffs, Harold Nathan et al. of San Francisco, were trustees under the mortgage of \$150,000, which was given as security on \$200,000 of the Quaker Hill company's 6% bonds. Unpaid interest on the mortgage amounted to over \$10,000. The mines are in active operation.

Portola.—Development work being done on the main-tunnel level of the Walker mine has established the fact that the gold and silver content of the ore is materially greater than in the upper levels. The ore is being stored on the dump; 10,000 tons of concentrate is awaiting shipment. Fifty men are employed. Improvements to the mill, consisting of the installation of a large crusher and the erection of larger ore-bins are under way.

Redding.—Twenty-four placer-mining claims totaling 3840 acres, have been located by interests connected with the Weed Lumber Co., of which J. M. White is manager. The claims are valuable for rich deposits of diatomaceous earth, which are said to be unusually free from iron.

COLORADO

Cripple Creek.—Recent shipments from the new discovery in the Lily vein at the 2000-ft. level of the Vindicator Consolidated company's No. 1 or main shaft, have brought settlement at from 10 to 12 oz. gold per ton. The shoot is reported opened for 350 ft. in length with a width of from four to five feet; 90% of the vein-matter is shipping-grade ore.

Some \$25,000 worth of ore has been shipped from the Hardwood claim of the United Gold Mines Co., on Ironclad hill, by T. R. Countryman and associates in the past seven weeks. The ore shipped ranges from 3 to 8 oz. gold per ton.—Good ore is reported from the Buena Vista vein of the Isabella Mines Co. at a depth of 1200 ft. The vein is about 3 ft. wide and the ore has been opened to date for about 75 ft.—High-grade ore has been opened by lessees on the fourth level of the Golden Cycle shaft of the Vindicator company.

De Beque.—The Monarch Shale Oil Co. has had its retort-plant in successful operation for three weeks. The company has contracts for supplying oil to be used in the flotation process. The Gibet furnace is used.

Durango.—The Mayday mines in the LaPlata district has been transferred to the Cumberland Mines Co., a Denver controlled corporation. The consideration is said to be \$100,000. The Mayday group of 14 patented claims has produced to date in excess of one million dollars. The controlling interest was held by the A. E. Reynolds estate. The property is fully equipped.—Cumberland Mines Co., organized in 1917, owns a group of claims eight miles from the Mayday group. A modern mill is now being built by the company, with a flotation unit, to handle milling ore developed on the Cumberland group.—Operations have been resumed on the Southern Boy, owned by Ralph Hutchinson, G. Stroebel, and G. Sheek. A rich strike was recently made on this property by lessees.—Lessees on the Idaho are mining and shipping smelting-grade ore to the Durango smelter.—The Clark group, situated near the Cumberland Mines property, is also active under lease.

Georgetown.—The Roosevelt Mining Co. has completed its new tram at Alice and is again operating both mine and mill. An orebody 75 ft. long has been opened on the Buster tunnel-level at a depth of 600 ft. from the surface and stoping has started.—The Rolland, on Brown mountain, has been leased for a two-year term. This claim was located in 1875.—The Silver Plume Consolidated Mining Co. is moving ore over the Snowdrift tramway to the company's mill.

Lake City.—The lessees on the Hidden Treasure mine, in the Galena district of Hinsdale county, are mining high-grade ore showing native silver, pronounced the richest ever mined on the property. The discovery was made in virgin ground with several hundred feet of ground above undeveloped. The Hidden Treasure lies north-east of the Ute & Ulay mine, that has produced in excess of \$11,000,000 and was operated several hundred feet below the deepest level of the Hidden Treasure. The lessees, McPolin and Halpin, should take out a fortune if the shoot holds as it is reported.

Telluride.—The Liberty Bell mine and milling plant were closed down last week and men laid-off. Mine equipment is being moved to the mill building for storage. The company's power contract having expired, the final mill clean-up will await thawing out of the Deer Trail water pipe-line when water-power will be substituted for electricity. The mine has produced steadily for 20 years.

Tiger.—The Tiger company is proceeding with the erection of a 300-ton mill and is sinking the I. X. L. shaft on its property 150 ft. farther to reach the 1000-ft. level. Other development is under way. Frank R. Wicks is general superintendent.

IDAHO

Coeur d'Alene.—M. J. Murphy, one of the owners of the Calumet mine $4\frac{1}{2}$ miles east of Burke, announces that work will be resumed as soon as supplies can be taken to the property.—It is reported that the cross-cut in the North Bunker Hill property, near Kellogg, is in 135 ft. from the bottom of the 500-ft. inclined shaft. In the last 10 days the

flow of water from the face has increased and it is believed the vein will be reached within 50 feet.

The Federal Mining & Smelting Co. has declared its second quarterly dividend this year. It amounts to 1½%, making a disbursement of \$210,000. The first quarter this year the company paid only 1%.—A raise will be run from the lower tunnel in the Silver Cable mine where good galena-zinc ore was found.—Improvement is reported in the orebody opened up in the West Sunset property. According to reports there is now five feet of high-grade silver-lead ore in the face of the drift that is being extended into the West Sunset mine. The ore was first entered in Sunset ground and was followed for more than 200 ft. before the drift entered the West Sunset holdings. The West Sunset group adjoins the Tamarack & Custer property.

Improvements are under way at the Jim Blaine property on Pine creek to cost \$2000. The group comprises 27 claims on Pine creek opposite the Nabob and is one of the oldest properties in the district. A tunnel, 600 ft. long, was driven in the upper workings where indications of lead-silver ore were found.

The mining interests in Idaho are demanding a tariff on all copper matte containing more than 7% lead imported to this country. The American Smelting & Refining Co. is seeking to have all copper matte containing up to 25% lead admitted free of duty. Representatives of Idaho's mines say that such competition would be injurious to the industry throughout the West.

MICHIGAN

Houghton.—With the shipment of 200,000 lb. of copper to Detroit last week, all metal orders on Calumet & Hecla's books, with exception of 200,000 lb. of wire bars, will have been filled. The C. & H. smelter is still operating though at less than half capacity. It has been working chiefly on special orders and if new sales are not soon made the plant will be shut-down entirely. A shipment of 1,200,000 lb. of copper was taken out this week by boat. This is a small consignment compared with usual cargoes. Of the amount 100 tons was Calumet & Hecla metal and the remaining 500 Copper Range and Quincy copper.

Seneca's developments on the 6th level, where the shaft is bottomed, continue to be encouraging. Both the north and south drifts opened 'rock' that compares favorably with the openings on the upper levels. The 3rd level drift, north, is proceeding in the direction of Gratiot with which it ultimately will connect. Stopping operations continue on the 4th level with satisfactory results. Until Seneca is equipped with new hoists in both shafts no further sinking will be done. In the Seneca levels, however, the drifts are extensive and afford ample opportunity for stopping operations and the blocking out of ground preparatory to regular production.

In the Mayflower mine all four drills are now employed in the east cross-cut from the 1700-ft. level. Work has been temporarily abandoned in the west cross-cut.

Mohawk is sinking in No. 4 and 6 shafts and drifting is under way in all four shafts, 1, 4, 5, and 6. Drifting is under way both north and south from the three bottom levels of No. 1. Southward, connection will be made with No. 4 shaft, enabling the extension of the electric haulage system to No. 1. It is the plan of Mohawk to conduct a complete program of sinking and drifting and to keep the mine well opened ahead. Mohawk has a large tract of ground yet to be opened, while many thousands of tons of rock remain in drifts and stopes yet to be widened or enlarged.

Ten men are employed by Calumet & Hecla in development work on the Kearsarge lode east of the 81st level of the Red Jacket shaft. A motor is used to haul the rock to the shaft. A steam-compressor has been employed in furnishing air for the drills but an electrical compressor shortly will be installed, which will cut down the cost of the

work considerably. Only rock of mediocre character has been found to date and the vein is not yet well defined. The formation, however, is to be thoroughly investigated.

MISSOURI

Joplin.—A ruling by Secretary of the Interior Fall is to the effect that new leases on Quapaw mining land "will not be granted until the expiration of existing leases and new regulations governing future leases will be promulgated under the recent Act extending restrictions". This will mean delay in the settlement of sundry disputes over rights in the Picher district. Sub-leases of the Eagle-Picher interests and other mining companies in the district will expire in 1922. In an attempt to renew the leases the Eagle-

Sullivan Mine in the Coeur d'Alene

Picher company made an offer to reduce the royalties to the sub-lessees, from 17½% to 15%, and many of the sub-lessees lent their support, by signing waivers. Most of the sub-lessees, it was said, favored the plan. Others, for various reasons, combined forces against the Eagle-Picher proposal.

MONTANA

Butte.—The Anaconda Copper Co. expects to employ 500 additional men in mining high-grade silver-zinc ore, which will be treated in the company's zinc-plant. It is expected that approximately 150,000 oz. of silver will be produced monthly. Consideration for the employees, who would otherwise be idle, helps account for the decision to resume.—Drifting on the recently discovered copper-bearing vein on the 2050-ft. level of the Butte & Superior mine has disclosed a considerable deposit of ore. A body 20 ft. wide and 100 ft. long, sprinkled with patches of ore, has already been opened.—Ore developments on the 2300-ft. level of the Colorado mine of Davis-Daly are particularly noteworthy, one body showing a width of from five

to six feet of 15% copper ore. Other deposits have been opened on levels above the 2500. It is stated that the ore showing at the present time in Davis-Daly's property is the best in its history. Lessees on the Hesperus vein, operating through the Butte-New England shaft, situated just to the south of the Colorado, are shipping several carloads of ore per week. A good revenue is assured for Davis-Daly from this operation in addition to accomplishing the development of the Hesperus vein in the south-easterly part of the company's territory.

At the Elm Orlu mine recent development discloses a large tonnage of silver ore carrying an average of 20 oz. per ton. Development work now in progress on the 300-ft. level indicates a good tonnage of milling ore. Steps toward raising the new shaft of East Butte to the surface are under way. This new shaft is above the 1200-ft. level and within 800 ft. of the surface. It will place the known orebodies of the East Butte within easy cross-cutting distance.

It is reported that the Norwich vein has been cut on the 400-ft. level by the Butte & Plutus Co. The vein was entered at a point about 325 ft. from the station, disclosing 7 ft. of 12-oz. silver ore. The Butte & Plutus is situated near the Hibernia mines of the Davis-Daly company.

Missoula.—Edward Mayo and associates report good progress in opening the Democratic group of claims in the St. Regis district.

Philipsburg.—The American Gem Syndicate has purchased 250,000 ft. of timber, to be used for making sluice-boxes for its operations in the Flint and Rock Creek districts. During the 1920 season the mines are said to have produced seven tons of sapphires, some of which were cut for rings; by far the largest amount went to watch manufacturers for jewel bearings.

NEVADA

Cow Camp.—Four miners are employed in prospecting the Sanger-Taylor group, on which the original discovery was made. The shaft on this group is 70 ft. deep and to this point assays ranging up to 1000 oz. silver have been obtained, according to Taylor. The district is four miles north-west of Stimler. Many locations have been made in the district and two miles from the Sanger-Taylor ground \$40 gold ore has been found. The vein in the Sanger-Taylor claims has an average width of 6 ft. in the shaft.

Eureka.—The Eureka-Holly Extension Co. has received its new hoist. It will be installed at the collar of the Standard 300-ft. vertical shaft on the Nevada No. 2 claim, where the principal operations of the company will centre. Bad roads have prevented an earlier delivery of this machinery. A cross-cut is being driven from the bottom of the incline near the south end line of the Belle of the West claim for the purpose of establishing the position of the Bullwhacker vein on this ground and its course through the Extension property. Exploration of the Silver West vein is also in progress. This is one of the strongest veins on the Extension property, showing a five-foot outcrop and a true unbroken course to the north-east through the Nevada No. 4 claim into the Nevada No. 2; apparently making for an intersection with the Holly and Bullwhacker veins near the west end-line of the latter claim.

The Ruby Hill Development company, a New York corporation which late in 1919 optioned the Eureka Consolidated and Richmond mines for a price said at the time to have been \$9,500,000, has relinquished the option, according to reports received here. The company, after cleaning and repairing the Locan shaft to the 1200-ft. point, the bottom, stopped work late in 1920. It had been the intention to sink to 1700 ft. The properties have reverted to the United States Smelting, Refining & Mining Co., owners of more than half the stock, and others.

Goldfield.—The shaft of the Deep Mines is being con-

tinued below the 500-ft. point with two shifts of miners. The funds derived from the recent assessment put the company in financial position to sink to at least 1000 ft., according to H. G. McMahon, secretary for the company. The Red Hill shaft, now 750 ft. deep, will reach the objective, 800 ft., by June 10 and a cross-cut will then be driven 150 ft. to cut the Florence vein system on the north side of the fault.

Hornsilver.—J. W. Dunfee, the lessee, refusing to accept counter-proposals to the original terms made by him, has terminated the option held by the Tonopah Mining Co. on the Orleans mine and the lease held by Dunfee, according to the lessee. The drift in which the find that led to the granting of the option was made has been enlarged at the face until there is now exposed an orebody 7½ ft. wide, 10 ft. high, and assaying more than \$40, according to Dunfee, who says the \$40 figure was obtained from an average sample.

Rochester.—The Rochester Silver Corporation has declared a dividend of 5c. per share, to be paid June 20 to stockholders of record June 15.

Tonopah.—The companies continue to import men in their efforts to break the strike; it now appears certain that they will be successful. Governor Boyle spent several days at Tonopah investigating conditions and attempting to mediate, but he was unable to make progress with the strikers, who on one occasion walked from the hall in which the Governor was to have addressed them following a vote. This vote was against taking a secret ballot on returning to work. The incident of the strikers refusing to hear the Governor turned public sentiment against them to a large extent. It is estimated that only 300 or 400 strikers remain in the town and it is reported that there are among this number many who are anxious to return to work, but who fear the taint of 'scab'. It is becoming increasingly evident that the trouble is going to end in a victory for the companies and that the complete breaking of the strike is merely a matter of time.

Virginia City.—There is much talk of labor trouble when wages are reduced under the agreement between the United Comstock and the Gold Hill miners' union and some of the men already have quit in anticipation. The new scale will be \$5 for miners. Zeb Kendall, president of the Consolidated Virginia and Ophir companies, has succeeded Alex Wise as superintendent. Wise resigned because of ill health following an operation.

SOUTH DAKOTA

Deadwood.—Roy M. Harrop, of Omaha, is here making arrangements to develop the property of the Capital Gold Mining & Milling Co., situated not far from the Trojan mine. Ore assaying \$6 per ton has been found near the surface.

TEXAS

Orla.—Mining and refining of sulphur is about to be started by the Toyah Valley Sulphur Co. whose property is near here. Machinery has been installed upon the sulphur deposit which the company owns and is now being given a test run. Outcroppings of sulphur which have been thoroughly explored cover several thousand acres of land which the company owns. Assays show that the product runs 20% to 97% sulphur. The company is operating under a patented refining process, developed by its secretary, J. A. Daniel.

UTAH

Big Cottonwood Canyon.—Work has been resumed by the Cottonwood Metal Mining Co., under the direction of E. E. Watrous. The face of the adit, now in 1410 ft. from the portal, will be driven until the intersection of the Silver King and Contention fissures is reached.

Eureka.—The Tintic Milling Co. shipped two lots of silver bullion during May, each of which contained about 50,000

oz. of silver, with some gold. The last shipment of copper bullion was in March. The company has a lease on the property of the Swansea Mining Co. and is preparing to mine the large quantities of low-grade ore exposed in that property, principally on the 500-ft. level. A new head-frame has been erected, and the shaft re-timbered to the 400-ft. level. Arrangements for automatic dumping are being made to permit the ore being dumped into cars of the Eureka Hill railway and transported to the milling company's bins.

Shipments from this district for the week ending May 21 totaled 128 carloads, of which the Chief Consolidated shipped 41; Tintic Standard, 41; Eagle & Blue Bell, 11; Dragon, 8; Swansea, 6; Iron Blossom, 5; Iron King, 5; Victoria, 4; Colorado, 4; Alaska, 2; Gemini, 1.

Midvale.—The United States Smelting company has awarded a contract to the Weider-Holt Construction Co. of St. Louis for the construction of a new smoke-stack at its smelter. The stack will be 450 ft. high and will cost \$150,000. It is being erected for the purpose of complying with the recent order of the Federal Court in the 'smelter smoke' case. By using a high stack, the fumes are carried to a level where they are thoroughly diffused so that damage to vegetation near the plant will be entirely eliminated.

Moab.—Howard W. Balsley, of the Yellow Circle Mining Co., has several men at work on the claims near Cane Springs. C. W. Wright, in charge of the work, has a carload of uranium ore ready for market. Several buyers are negotiating for the output. Mr. Balsley has on display here one of the finest specimens of uranium ore ever found in this district. The sample weighs about 15 pounds, and averages 25%.

L. C. Schultz and J. S. James of Denver are in this district in connection with the affairs of the Radium Company of America, which recently took over the Tungsten Products Co. It is understood that the Radium Company is planning the construction of a mill in Dry Valley to handle carnotite ore.

Park City.—Ore shipments from this district for the week ending May 21 totaled 1651 tons, as compared with 1545 tons for the preceding week. The Silver King Coalition shipped 766 tons; Judge allied companies, 467; and the Ontario Silver, 418.

Development work is being done at the property of the Ontario Silver Mining Co. The 400-ft. level has been reopened to No. 1 shaft and is being continued to the east toward the 'great' fault. Prospecting is also being done on the 1300 and the 1800-ft. levels. The 2000-ft. level has been unwatered, after twenty years. The workings at this depth have been cleaned out and re-timbered, and preparations are being made to tap, from this level, the orebodies developed on the 1800-ft. level.

Salt Lake City.—The Supreme Court of the State of Utah undertook the review of the case of the Utah Copper Co. v. the Utah Power & Light Co. on May 23. The case is of considerable length and somewhat complicated, and involves the authority of the State Public Utilities Commission to interfere with a contract made prior to the creation of the Commission. Since October 22, 1920, the mining company has been billed at practically double the rate provided for by the contract. The difference between the contract rate and the schedule rate between October 22 and March 31 would have amounted to about \$200,000 in the consumer's power bills. R. G. Lucas, attorney for the Utah Copper Co., declared that his company can make power in a steam-electric plant for about 5 mills per kilowatt-hour, as compared with the rate, fixed by the Commission, of more than 8 mills.

WASHINGTON

Colville.—Development work at the Chloride Queen, one of the oldest mines in the district, has been satisfactory.

There is sufficient milling ore in sight in the upper adits to run a concentrator five years or more, but in order to tap the vein at depth work was commenced last December on a lower adit to run 526 ft. to the vein. The Chloride Queen ore assays from \$10 to \$20 per ton. D. E. Zent is directing development.

Keller.—At the property of the Iron Creek Mining Co., 12 miles north-east of here, a new vein has been found that carries 25.4 oz. silver per ton. It has been opened for 15 ft. on the surface and is 1½ ft. wide. Work will commence at once on construction of the foundation for the cyanide plant. The ground is already cleared.

Miles.—J. C. Hammond is driving a tunnel south of, and immediately above, Fort Spokane, where he hopes to cut the Crystal vein, which contains some silver and lead.

Republic.—Lower freight-rates, re-established by the Great Northern railway, will go into effect at once and im-

Tramway at Britannia Mine, Howe Sound, B. C.

mediately some ore shipments will be made. Republic ores are wanted by smelters for their value for fluxing. For this reason they pay a good price for them. It is reported that the Northport Smelting Co. has made a contract to supply the smelter at Trail with 10,000 tons of ore from its mine here. The Northport company is not operating its own smelter and there is no prospect of an early resumption. —Lessees have been working the Knob Hill property and have ore ready to ship.—The San Poil has 3000 tons ready for shipment.

BRITISH COLUMBIA

Alice Arm.—C. B. North, manager for the Taylor Mining Co., arrived from Vancouver, and has gone to the Dolly Varden mine to make a survey of the company's property. Mr. North said he was not able to give any information about the future plans of the company, but he believed much would depend upon his report. If work is re-started, he thought it probable that, for a long time at any rate, it would be confined to development, rather than to production. The main effort during last season was toward production, the intention of the directors being to catch up with the development during the winter, when shipping is impossible.

Barkerville.—The affairs of the Bullion mine are once again in the courts. A writ has been issued by R. T. Ward, on his own behalf and as manager for the Bullion Mining Syndicate, against W. C. Daniels, Stanley P. Dunlevy, and Max McGowan, asking for an injunction to restrain them from trespassing, interfering, or in any way dealing with the plaintiff's interests in the Bullion mine, water-rights, dams, and other property of the syndicate.

Hedley.—G. P. Jones, general manager for the Hedley Gold Mining Co., has returned to Hedley, after an absence of some six months, and is re-opening the Nickel Plate mine. Repairs are being made to the flume, and some slight damage caused by the spring freshets is being mended. At first the operations will be confined to development, which had fallen in arrears in an effort to produce as much gold as possible during the War.

Stewart.—The strike at the Premier mine has been settled, and the men have returned to work at a uniform reduction of 75 cents per day. Miners now are receiving \$5.50, muckers \$5, and laborers from \$4.75 to \$5.—Robert Martin, one of the principal owners in the Mineral Hill group, recently paid a visit to the property for the purpose of arranging for development work on the property during the coming season.—Crawford McGee and R. E. McKechnie, of Vancouver, have arrived to start operations on the Patricia group, on the Marmot river. Some tunneling was done on the property last season, and a considerable body of ore, the extent of which was not determined, running \$12 in gold and \$10 in silver and lead, was discovered. This orebody is to be thoroughly explored this summer.

KOREA

Unsan.—At the Oriental Consolidated property 160 stamps ran 22½ days during March, crushing 17,235 tons of ore. Gross receipts for the month were \$109,644, with a net profit of \$31,327.

MEXICO

Chihuahua.—Carlos Perez is said to have found radium-bearing mineral, analysis of which has been made in the United States. The mines from which samples have been taken are situated in the Guadalupe district.

Guanajuato.—On May 8, the Governor of the State made public in full the law of Conciliation and Arbitration, which was passed by the State Legislature during the latter part of April. This law affects all employers of labor in the State, but is of particular concern to the mining companies, as they are the largest employers of labor. The following gives a brief outline of the law:

Each municipality is to choose a Board of Conciliation and Arbitration, labor furnishing one member, capital another, and a third member is to be chosen by the municipal government. This board is to attempt to settle disputes and conflicts arising between capital and labor; either side may have it called to a session or it may be called on the initiative of the chief municipal officer of the place, called the 'Presidente'.

In the State capital, a central board will be created, consisting of five members chosen by capital and five chosen by labor and one representing the executive of the State. The members of this board will be chosen for one year and will function permanently; cases that cannot be settled by the municipal boards may be appealed to the Central Board. Both boards will attempt to settle disputes in the shortest possible time; the law specifically states that five days time will be given for the review of the cases brought before the boards. The following penalties will be incurred by the side refusing to abide by the decision of the board:

Article 36. If the employers refuse to carry out the decision of the board they must pay all the laborers engaged in the conflict three months wages, the labor contract being terminated.

Article 37. If the workmen refuse to carry out the decision of the Board, their labor-contract is thereby ended and the authorities will take measures necessary to guarantee the employers liberty to make new labor-contracts without having the new laborers molested in the fulfillment of their duties.

Article 45. The owners of mines, reduction works, shops, industrial establishments, and in general all employers of labor, must send to the Central Board for its approval all rules of their establishment each time they are put in force.

Saltillo.—Francisco Salas is to develop the Estella group of zinc mines in El Aguajera mountains near Saltillo. The property is near the San Antonio mines which are at present idle on account of the low price of metals and the lack of railroad facilities.

About nine thousand additional mining claims are listed by the Government for forfeiture unless taxes are soon paid. Many of the properties will be re-located by new owners immediately after being declared open for re-filing.

Soyopa.—A discovery of rich gold and silver ore is reported at the Hidalgo mine. Specimens brought to Nogales assayed 157 oz. of silver and ¾ oz. of gold per ton. J. E. Crocker, manager for the Soyopa Silver Mining Co., owner of the property, declares it to be one of the most important finds made for some time in Sonora.

ONTARIO

Elk Lake.—An important discovery of iron ore has been made within fourteen miles of Elk Lake by B. M. Hartley, formerly field man for the Kerr Lake Mining Co., and H. Wescott of Elk Lake. Massive hematite containing 64 to 70% iron appears in one band four feet in width and at least 150 ft. in length; four large dikes, ranging from 17 to 25 ft. in width of quartz and jasper run in a series and the general assay taken showed 55.78% iron, 19.06% silica, and 0.07% phosphorus. The formation is sedimentary, conglomerate and slate being in evidence, and the pebbles in the conglomerate being well-rounded. About 140 lb. of ore was removed; it is almost identical with that of the Gogebic Range in the Lake Superior region.

TORONTO

Porcupine.—The annual report of the Dome Mines for the year ended March 31 shows net profits of \$302,479, as compared with \$951,984 in the previous year, the falling off being due to the difficult conditions under which the industry was carried on by reason of scarcity of labor and power shortage. During the first three months of 1921 costs went up to \$5.03 per ton, while in April when electric power became again available they dropped to \$3.75 per ton. The 273,700 tons of ore milled during the year yielded bullion worth \$1,946,403, the average yield per ton being \$7.11. Dealing with the results of drilling on the 10th level revealing the value of an orebody dipping into the Dome Extension H. P. Depencier, general manager, points out that assays showing \$26 per ton do not represent the average grade of ore that can be expected from that body.—The McIntyre is sinking to the 2000-ft. level from its present workings at 1550 ft. below the surface, the ultimate objective being a depth of 3000 ft., which, however, may require a couple of years to accomplish.—Last year English interests undertook the exploration by diamond-drilling of the sand plains in the neighborhood of the Hollinger. Several drill-holes were put down, but the work was discontinued during the winter and has not been resumed. Americans have recently taken over many of these claims under option and are preparing to drill. The sand lies two to three hundred feet deep over the rock formation into which it is thought some of the Hollinger veins may extend.—The Goldale Mining Co., which has acquired part of the Bewick-Moreing holdings, is arranging to carry on exploration under the supervision of C. A. Poirier of New York.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. F. Ferrier, of Toronto, is at Vancouver.

W. H. Whittier is at Barranquilla, Colombia.

H. G. Thiel has left San Francisco for Oklahoma.

Waldemar Lindgren will spend the summer in Bolivia.

E. P. Mathewson sailed from Liverpool for New York on May 25.

J. M. Ruffner, of Atlin, British Columbia, is here for a few days.

J. T. Kavanagh, of Valley, Washington, is at El Dorado, Arkansas.

L. D. Ricketts and **John C. Greenway** were in New York last week.

Charles R. Davies, of Denver, Colorado, is at Salt Lake City, Utah.

E. A. Knapp, of Redruth, Cornwall, has gone to Maracaibo, Venezuela.

X. B. Stearnes has moved from Morenci, Arizona, to Berkeley, California.

Thomas W. Thompson has moved from Shafter, Texas, to Berkeley, California.

Thomas M. Skinner Jr. has moved from Douglas, Wyoming, to Denver, Colorado.

Carlton D. Hulin has returned from Maracaibo, Venezuela, to Alameda, California.

L. D. Yundt, of Salt Lake City, is now with the Ramshorn Mines Co., at Bayhorse, Idaho.

C. G. Patterson is on his way to Nicaragua, to erect a stamp-mill at the San Albino mine.

C. S. T. Farish has left Mexico, to join the Backus & Johnston company at Casapalca, in Peru.

George H. Garrey, who recently returned from two months in British Columbia, is now at Tonopah, Nevada.

Joseph Irving, of Bisbee, is in charge of leaching experiments for the Dundee-Arizona Copper Co. at Jerome, Arizona.

Gordon Campbell, formerly secretary and treasurer of the New Cornelia Copper Co., has been elected president of the company.

A. W. Newberry returned to New York on May 27 after three weeks spent in visiting Cleveland, Chicago, Washington, and Baltimore.

Arthur Notman, superintendent of the mine department for the Phelps Dodge Corporation, at Bisbee, Arizona, is at Keene Valley, New York.

Veleair C. Smith, mining geologist for the Cia. Mexicana de Petroleo 'El Aguila', S. A., at Tuxpam, Vera Cruz, Mexico, is at Elizabeth, New Jersey.

B. V. Barton, lately at Bendigo, Victoria, has accepted the position of assistant-manager to the Rhodesia Broken Hill Development Co., in Rhodesia.

John Bendel, who has been with the Alaska Juneau Gold Mining Co., at Juneau, Alaska, has gone to Oroya, Peru, with the Cerro de Pasco Copper Corporation.

R. W. Brock, Dean of the University of British Columbia, and **J. J. Denny**, of the Nipissing mine, have received honorary degrees from Queen's University, Toronto.

Arthur H. Wethey, formerly at Butte, and now residing in Paris, was in San Francisco this week in the interest of the Fund for War Devastated Villages in France.

Frank M. Gallup, of Sandusky, Ohio, is at Crestone, Colorado, convalescing after a bad attack of asthma resulting from influenza, from which he suffered last March.

Charles L. Harrington, field engineer for the Radium Com-

pany of Colorado, has been transferred to Grand Junction, Colorado, where the company has opened new offices.

C. Algernon Moreing, of the firm of Bewick, Moreing & Co., London, has received the Order of the Legion of Honor from the French government on account of his services during the War.

D. D. Moffat, consulting engineer of mills for the Jackling porphyry properties, spent several days in San Francisco recently. He will visit the Chino and Ray properties before returning to Salt Lake City.

Carl J. Trauerman, formerly manager for the Liverpool Silver Mines Co., at Clancy, Montana, is now in the oil-stock department of the Lauzier-Wolcott Co., the Butte correspondents of Logan & Bryan, of New York.

A. H. Lowe, chief geologist for the Mackenzie River Oil Co., has left Edmonton with a party of six men for Peace river, when he will take the first boat to the oilfields at Fort Norman. He plans to stay a year in the North, and will locate sites for the company's boring operations.

M. W. von Bernewitz has completed editing the 1920 proceedings and original papers from the Denver meeting of the American Mining Congress, and is now temporarily engaged with the U. S. Bureau of Mines at Washington, compiling matter to be used by the Bureau in its campaign of technical education in mining regions.

Dorsey A. Lyon, superintendent of stations for the Bureau of Mines, and **George S. Rice**, the Bureau's chief mining engineer, are to leave Seattle on June 25 for Alaska, where they will investigate conditions in connection with the mining industry generally, and will determine the manner in which the Bureau's station at Fairbanks can best serve the interests of the industry.

Obituary

R. T. Lowery, for many years editor and owner of 'The Ledge', one of the oldest mining papers in British Columbia, died at the Greenwood hospital on May 20, aged 65.

Arthur Lancaster, foreman of the concentrating plant at the United States smelter at Midvale, Utah, was instantly killed on May 21, when his clothing was caught in a fast-revolving shaft and he was crushed before the machinery could be stopped. He had been with the company since the plant was built at Midvale. He is survived by his wife and three children.

Donald W. Cooke, of the U. S. Bureau of Mines station at Berkeley, died suddenly on May 27. He was a native of Washington, served in the army during the War, and since the Armistice was connected with the Bureau of Mines at the University of California, where he was engaged in training miners, boy scouts, and industrial workmen in first-aid and mine-rescue work. He was only 27 years of age.

William Fernie, 84 years old, pioneer prospector, mine operator, and railway promoter, died in Victoria on May 15. The City of Fernie, B. C., was named after him and he was the original discoverer of coal in that district. His first work as a mining man was done in the Australian mines of Bendigo and Perdue. He came to British Columbia in 1860 and was engaged in mining for many years. In 1873 he was appointed Gold Commissioner for Canada, a position he held for four years. On resigning he joined Col. C. Baker and other western Canadians in the effort to obtain a charter for the British Columbian Southern railway. In this he and his confreres were successful, and in 1887 he located the coalfields of the Crow's Nest Pass. With the opening of these fields there grew up in that locality the now flourishing community of Fernie, which, as stated, was so named in honor of the man primarily responsible for its existence.

THE METAL MARKET

METAL PRICES

San Francisco, May 31

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	6.75
Copper, electrolytic, cents per pound.....	13
Lead, pig, cents per pound.....	5.25—6.25
Platinum, pure, per ounce.....	\$75
Platinum, 10% iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$50
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	9.00—9.50

EASTERN METAL MARKET

(By wire from New York)

May 30.—Copper is quiet and firm. Lead is inactive and lower. Zinc is dull but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

DECLINE IN COMMODITY PRICES

Recent increases in the wholesale prices of certain commodities do not indicate a new period of rising values, in the opinion of Herbert P. Howell, vice-president of the National Bank of Commerce in New York. They do, however, show that the violent general decline in raw materials is definitely at an end. Many individual commodities will show considerable further revisions, he believes, but the general movement has reached a level at which manufacturers may do business on the basis of their own requirements irrespective of the market prices of unrelated commodities.

"Of the 26 representative commodities quoted monthly by the National Bank of Commerce in New York in its magazine, 'Commodity Monthly,' Mr. Howell points out, 'sixteen showed increases in May over the preceding month, while four stood still, and only six continued to decline.'

"These increases must not be construed as indicating a new period of rising prices. Some of them are seasonal in character and others reflect a tendency toward stabilization on the part of commodities which in the general decline that began in the spring of 1920 may have fallen below a fair valuation. The increases are important, however, because they demonstrate that the process of liquidation has reached a point where raw materials are beginning to react to conditions in their own individual markets.

"Normally the price movement of every commodity is determined primarily by the status of its own market and that of commodities immediately related to it. Only in boom periods or during violent depressions are prices affected more by the general movement than by these individual factors. What has happened now is a return toward normal conditions. Henceforth, commodities may be expected to fluctuate in obedience to the influences of specific supply and demand.

"Many prices have stabilized. This does not mean that there will not be further declines. They may be expected in many lines, and commodities which have not yet been adjusted will receive no support from others that have reached a stable footing. In their decline, they will not force down commodities in which deflation has already occurred.

"Index numbers have not yet disclosed the end of the general price-change in the market for raw materials, due to the fact that all such numbers in use contain quotations for a large number of commodities in fairly advanced stages of manufacture and in some cases ready for consumption. There is a considerable lag between declines in raw materials and in finished goods, and when quotations from these two groups are combined the declines in manufactured goods are sufficient to obscure the trend of basic material prices.

"While the violent general decline in raw materials and related products is over, this does not preclude a slow decline for a period of years. Such a decline would be no menace to sound business. It is perfectly possible in such a period to carry on sound manufacturing and merchandising operations with profit. Gradually falling prices over a period of years would not materially affect the price-movement of commodities over such periods as are usually necessary for these operations. The present generation of American business men has been unduly alarmed by the downward tendencies of prices. Rising prices are not necessary to prosperity, and a slow downward movement is discouraging only to reckless speculative activities."

MONEY AND EXCHANGE

Foreign quotations on May 31 are as follows:

Sterling, dollars:	Cable	3.88 1/2
	Demand	3.89 1/2
Francs, cents:	Cable	8.37
	Demand	8.39
Lire, cents:	Demand	5.30
Marks, cents	Demand	1.65

Eastern Metal Market

New York, May 25.

All the markets are quiet except copper; it is more active and by far the strongest.

Foreign buying of copper continues and prices are higher.

The tin market is quiet and without feature.

Demand for lead has lessened and the market tone is easier.

The zinc market continues lifeless and prices have declined a few points.

IRON AND STEEL

The further slowing down of operations at iron and steel plants, as well as of new buying, has dispelled any hope recently entertained of an immediate turn for the better, according to 'The Iron Age'. In the industry attention is centring upon the reduction in railroad wages, ranging from 10 to 15%, effective July 1, as making possible the lower freights which are now expected to bring such further readjustment in iron and steel prices as will start business. Opinion is uniform that freight-rates are coming down, but the belief that this may be some months hence points to light buying of steel products meanwhile, as no stock will be accumulated on today's prices. Meanwhile, the railroad-wage reductions are regarded as a favorable factor, in view of the easier financial condition of the railroads in the second half of the year. The failure of many railroads to pay their steel bills has tightened the finances of not a few mills.

COPPER

There are reports that buying of copper for export last week totaled 25,000,000 lb., but it has not been possible to confirm this. There is no doubt, however, but that foreign buying by all the leading countries of Europe and the Far East has been heavy and perhaps heavier than a week ago. Domestic business is better, but by no means active. Prices have stiffened at least $\frac{1}{2}$ c. per pound and in some quarters more than this. The minimum on electrolytic copper for June delivery is 13.50c., delivered, with some asking 13.75 and 14c., delivered. Foreign sales are in most cases made at $\frac{1}{2}$ to 1c. higher. Lake copper is also higher at 13.25c., New York, or 13.50c., delivered. Export demand is so good that foreign agents of American sellers are being limited as to the amount they can sell. Both the Export Association and outside sellers have participated liberally in foreign sales, some saying that England has been a good buyer; others that France, Germany, and others are their chief customers. The market tone is strong.

TIN

The market has been practically inactive excepting one day—on last Thursday, May 19, about 150 to 200 tons of future shipment and spot Straits tin was sold at around 33c. for both positions. The only other feature was the slump in exchange in London on Monday, May 23, which lowered values of tin here as well as there. The decline in sterling is ascribed to the Silesian matter. Yesterday values in London fell about £3 per ton from Monday's level, with spot standard quoted yesterday at £181, future standard at £181 10s. and spot Straits at £185 per ton. These values, however, are not much below those a week ago today. After hanging at 33 to 33.25c., New York, spot Straits fell Monday to 32.75c. and yesterday to 32.25c., New York, sales having been light. Arrivals thus far this month have been 315 tons with the quantity afloat reported as 2075 tons.

LEAD

Buying has subsided and a little easier tendency has developed, the market being quiet and dull and without any

feature. The American Smelting & Refining Co. has not changed its quotation of 5c., New York and St. Louis, but in the outside market values are lower at 4.80c., St. Louis, or 5.10c., New York, which we quote as the market, most business going at these prices. The relation between consumption and production may have changed recently because at 5c. it would pay to produce, and a resumption in some cases has probably taken place.

ZINC

Softness continues to develop in the market for prime Western, which today is quoted at 4.75c., St. Louis, or 5.25c., New York, for early delivery. Demand is confined to small lots here and there for hand-to-mouth needs. Several large sellers will not quote at present levels and prices for forward delivery are practically unobtainable. Germany has been supplying most of the needs of England in recent months, which has cut down American export demand, but the importation of an export tax in Germany may change this condition in favor of American zinc.

ANTIMONY

The market is quiet and without change, with wholesale lots for early delivery quoted at 5.25c., New York, duty paid.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, for early delivery are quoted by the leading producer at 28c. f.o.b. plant, while the same grades from foreign makers are easier at 22.50 to 23c.

ORES

Tungsten: No decided change is reported. Buyers' and sellers' ideas of prices do not harmonize and therefore inquiries, which are moderate in volume, do not result in much business. Quotations range from \$3.25 to \$4 per unit.

Ferro-tungsten is quoted lower at 48 to 58c. per pound of contained tungsten in lump form guaranteed.

Molybdenum: No demand is reported and quotations are nominally unchanged at 45 to 50c. per pound of MoS₂ in regular concentrate.

Manganese: Stocks are heavy and importations very large on contract, so no business develops. Quotations are nominal at 22.50c. per unit, seaboard, for high-grade foreign ore.

Manganese-Iron Alloys: Demand for ferro-manganese is confined to a few carload lots. Quotations are \$80, delivered, for the American product and \$75, Atlantic port, for the British. Spiegeleisen is quiet at \$30 to \$32, furnace.

Manufacturers must be prepared to meet the cry for lower prices, states the 'Electrical World,' not necessarily because their prices are unduly high, but because other commodities, which have hitherto been out of reach, are beginning to approach normal. The public is inclined to believe that all manufacturers have profiteered, and the burden of proof therefore will be thrust on the producer. Unreasonable demands will be made on the industry, and these will have to be dealt with sympathetically but firmly. If it is possible to grant reductions or better terms, these should be given, and if business can be re-started by taking some losses, it may be the part of wisdom to bear them. But it is shortsighted to put artificial props under trade and industry in an effort to prevent readjustment. It will also avail nothing to offer goods at cost or less if there are no takers.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

Brass sheets, half-hard and soft, per pound.	0.30
Drill-steel, hollow, first grade, in ton lots, per pound.	0.18
" " " solid " "	0.11
Fish-plate bolts, ½ by 2-in., per 100 lb.	9.30

Nails and spikes (20d to 60d base), per keg.	5.25
Nuts, hot pressed, ¾-in., hexagonal, per 100 lb.	11.25
" " " cold punched " "	13.20
Picks, mining, 5-lb., per dozen.	12.00
Shovels, carbon steel, No. 2, long handles, per dozen.	18.00
Track spikes, per 100 lb.	6.10

HEAVY STEEL AND PIPE

Bar steel, soft, per 100 lb.	4.35
Rails, steel, 8 to 25-lb., per 100 lb.	4.60
Reinforcing-steel, per 100 lb.	4.35
Sheets, corrugated, galvanized iron, 26-gauge, per 100 lb.	7.80
" " " flat " "	7.70
" " " flat, black iron " "	6.90
Structural T's, channels, angles, and beams " "	4.35
A deduction of 15c. per 100 lb. is made on the above when purchased in carload lots.	
Bars, steel, square, cold-rolled, per 100 lb.	7.50
Pipe, wrought-iron, black, standard, 1½-in., per 100 ft.	13.80
" " " galvanized " "	17.20
" " " black " 4-in. " "	61.05
" " " extra strong " "	116.75
Shafting, cold-rolled (2½ to 3-in. base) " "	6.25

HOISTING-ROPE

Discounts for delivery from Pacific Coast stocks are: cast-steel, 17½%; extra strong cast-steel, 25%; plow-steel, 30%; blue-centre steel, 15%. The following illustrations indicate the net price for each kind of rope, in standard, 6-strand, 19-wire, 1-in. rope.	
Blue-centre rope, per foot.	0.42½
Cast-steel rope, per foot.	0.25½
" " extra strong, per foot.	0.28
Plow-steel rope, per foot.	0.30

LUMBER

The figures given are subject to variation, depending upon the size and length. A charge for cartage is also to be added. Prices are furnished by Van Aredale, Harris Co.	
Fir, No. 2 clear and better, 1 to 2 in. thick, up to 16 in. wide, per thousand feet (M)	90.00
Fir, common, base price, per M.	30.00
Fir, common, 6 by 6-in. up to 12 by 12-in., per M.	36.00
Redwood, rough merchantable, 1 to 4 in. thick, per M.	50.00
" " clear, 1 to 2 in. thick, up to 12 in. wide, per M.	100.00
Spruce, "B" and better, 1 to 2 in. thick, up to 16 in. wide, per M.	90.00
Sugar-pine, No. 1 and 2 clear, 2 in. thick, up to 16 in. wide, per M.	200.00
White pine " " " "	180.00

MISCELLANEOUS

Air-hose, 1-in., 5-ply, plain, per foot.	0.48 to 0.65
Candles, "Granite" mining, 6-16-40, 10-case lots, per case.	7.10
Carbide, in 100-lb. cans, per can.	7.75
Cotton waste, best grade, per 100 lb.	16.25
Diamonds for drilling, according to size, per carat.	50.00 to 75.00
Manila rope, grade 1, per pound.	0.19
" " " 2 (standard), per pound.	0.18
Packing, flax, per pound.	0.50 to 1.00
" " sheet " "	0.35 to 1.00
" " steam or water, first grade, per pound.	1.00
Silex lining, crated, per long ton.	35.00
Tube-mill pebbles, Danish, selected (in bags), per long ton.	30.00
Zinc-dust, in 250-lb. boxes, per 100 lb.	9.50
" " sheet, 36 in. by 84 in., in tons lots, per 100 lb.	14.50

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000, in carload lots.	60.70
Fire-clay, in bags, per ton.	18.00
Lime, lump, in barrels, per barrel of 180 lb.	3.25
Portland cement, in bags, per barrel of 380 lb.	4.20
Allowance of 15c. for bags returned in good condition.	
Portland cement, in barrels, per barrel of 400 lb.	5.50
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time. This list is corrected monthly by Atkins, Kroll & Co.	
Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %.	60c.
Asbestos (crysotile), according to length of fibre, per ton.	\$20 to \$2500
Barite, white and free of iron (crude), per ton.	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi.	12
Feldspar, crude, lump, free of iron, per ton.	5 to 10
Fluorspar, 85% calcium fluoride, per ton.	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton.	5 to 10
Graphite, crystalline, per pound.	3c. to 7c.
Magnesite, calcined, per ton.	25 to 35
Manganese ore, less than 0.75% Fe; less than 6% SiO ₂ , per ton.	25 to 30
Mica, according to size, cleanness, and cleavage, per pound.	1 to 8
Molybdenite, not less than 85%, free of copper, per % MoS ₂ .	8 to 12
Ochre, according to strength, crude, per ton.	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton.	15 to 18
Talc, lump, white, per ton.	7.50 to 10
Tin ore, not less than 80% Sn, per % Sn.	5
Tungsten ore, not less than 65% WO ₃ , per % WO ₃ .	2.75 to 3.00

IN OUR news columns will be found a summary of the report of the Committee on Revision of the Mining Law that was submitted recently to the Director of the Bureau of Mines. This report is to be the basis for a proposed new code of mining law. The complete report, together with editorial comment, will appear in a later issue.

GOVERNMENT appointments on a non-political basis are so entirely desirable that we welcome the Bill, recently introduced by Representative McFadden, that has for its purpose the creation of a permanent Under-Secretary of the Treasury and the abolition of the office of Comptroller of the Currency. The new Under-Secretary would receive additional emoluments, commensurate with his position as a trained man and as an authority on finance and taxation.

IN reviewing the trend and maintenance of high prices during recent years it is interesting to refer to an exception to the general tendency, in the case of oxygen. The use of this gas has increased so largely during and since the War that scope has been found by the principal producers for improvement in the manufacture and for cheapening the production; the result being that the cost to the consumer has been lower during the intervening time than it was in 1915. To this fact is due, in no small measure, the increased use of a combination of oxygen and acetylene for welding and cutting metals, and the extension of the application of the oxy-acetylene torch to all phases of engineering work.

FROM Gowganda, a mining district of promise in Northern Ontario that suffers from the lack of railway communication, comes the novel suggestion that a satisfactory substitute for a railroad might be a track of light steel rails on which motor-trucks could be operated economically. Mine operators have urged the Provincial government to extend the Elk Lake branch railway to Gowganda, but such a project is not warranted at the present time, according to the officials. The recent suggestion is that the Government be approached with a proposal that it help to finance the laying of light rails suitable for motor-truck traffic. We are not familiar with local conditions and do not know, therefore, what obstacles there may be to interfere with efficient transportation by truck on an ordinary high-

way. Apparently an opportunity for an interesting comparison offers itself to auto-motive engineers to determine the comparative economy of the two systems, taking into account such factors as first cost, maintenance, depreciation, and operation.

DECLINES in the cost of production and manufacture are not felt by the consumer until some time after they have occurred. The wholesale prices of commodities are declining slowly but steadily; the Bureau of Labor Statistics reports a drop of 5% in April, as compared with March. The April 'index' figure is nearly 42% below that of April 1920, and nearly 43½% below the peak of last May. The same Bureau states that the retail cost of food to the average family in the United States during April was 2.7% less than it was during March. However slow the reduction in the cost of living may be, a further steady decline is inevitable. With the approach of 'normalcy' the law of supply and demand will affect, if not control, the situation.

JUNE 1 was the date set for the reduction of prices by the manufacturers of many commodities; our friends in the 'powder trust' joined the procession by reducing the price of explosives by about 10%. This will be good news to the miners, who have cherished a particular grievance because powder has heretofore cost them almost as much as it did during the War. To give the devil his due, however, it may be mentioned that the war-price of explosives was not as high, in proportion, as that of sundry other necessities. Nevertheless the manufacturers of powder reaped plentiful profits when the cost of labor and raw materials was two or three times what it is today; it is evident therefore that the recent reductions were in order, and that a still further readjustment downward ought to be forthcoming later.

OF the many towns affected by the recent shut-down of the copper mines, perhaps none is more interesting than Tyrone, New Mexico, where the Burro Mountain mine and concentrator of the Phelps Dodge Corporation are situated; nor has any suffered more seriously from the suspension of operations. As a mining camp Tyrone is unique. A touch of romance is lent by the fact that Mrs. Cleveland H. Dodge was godmother to the town; it was largely through her influence that

attractive bungalows were built as miners' homes. The 'shanty town' that mars the appearance of most Western mining settlements is lacking. The company houses are not built from a standard pattern, but each is artistically designed to follow the southern Californian type of architecture; the railroad station is said to be the most beautiful in the State. Here a few months ago 4500 busy people led contented and thrifty lives; now only the watchmen and their families remain. The homes are deserted; the general store owned by the Phelps Dodge company is closed and its stock has been shipped to Bisbee; the great power-plant, the mill, the compressors, and the hoists are pathetically silent; even the railroad company has announced that train service on the branch line to the Santa Fe will be discontinued. May the time be short before the whistle that calls the miners to work is again blowing regularly, and the bungalows of Tyrone are buzzing with the voices of happy children!

COMPLAINT is often voiced, by those of us whose professional work takes us abroad, that we do not get adequate or satisfactory assistance from our consular representatives. This may be due, in no small measure, to our own faults; it is certain, however, that a reciprocal interest will help to quicken the mutual feeling that should arise between a stranger to, or a foreigner in, a country, and his country's representative. The Mining & Metallurgical Society of America is doing a service in asking its members to communicate with the secretary in regard to intended professional visits abroad; the Secretary of State will then be advised, and this information will be passed, through official channels, to the consular and diplomatic representatives in the districts to which the engineer intends to go. This will be of mutual benefit. The engineer will possess satisfactory introductions; the plan will enable the Department of State to keep in touch with professional men who can be of service to the Government's representatives in foreign countries. The personal contact will engender a degree of mutual respect and co-operation that is now somewhat lacking.

OPINIONS differ as to the results of decreasing the number of working hours in a week. In some instances a marked increase in efficiency is reported; in others, the reverse. The National Industrial Conference Board has recently issued a report that deals with the results of an extensive investigation of conditions in 436 manufacturing establishments in which, since the beginning of 1919, the weekly schedule of working hours has been reduced to 48 per week, or less. The number of workers included in the investigation was 373,536; a variety of industries was represented, some small, some large. In 87.2% of the establishments a reduction to a work-week of 48 hours or less was accompanied by a decrease in the weekly output per worker; in 8.7% of the plants the workers maintained weekly production; in a very few cases (4.1%) the weekly output per worker was increased. It was found that, in those industries where highly automatic production predominated, the output

was governed almost entirely by the speed of the machine, as might be expected. In other industries, where hand-work predominated or where the skill and speed of the worker in handling machines were the controlling factors, it was possible to increase the output in some cases to the extent of entirely compensating for the loss in work-time by the substitution of shorter hours.

AN interesting feature of the new plant, of 200 tons daily capacity, at the Luz mines of the Guanajuato Reduction & Mines Company, which was completed during December last, is the large amount of concrete that was used. The mill, according to the annual report, is of the all-sliming type. The ore is broken in rock-crushers, and then passes to a battery of 25 stamps, each of 1150 pounds. The pulp is further reduced in a 5 by 5-foot ball-mill, and finally slimed in three 5 by 16-foot tube-mills that operate in closed circuit with Dorr classifiers. Five 36 by 10-foot Dorr thickeners are used, in conjunction with diaphragm pumps, for the impoverishment of the pulp by a system of counter-current decantation, the agitation of the pulp and the dissolution of the metals being effected in four 36 by 12-foot Dorr agitators. The surplus solution from the tailing pond is pumped back to the plant circuit. The Merrill-Crowe system is used to precipitate the gold and silver from the cyanide solution. Reinforced concrete has been used throughout the cyanide plant—for the construction of the thickeners, of the agitators, and of the storage vats. In some cases it was found possible to utilize the upper sides of the vats as retaining walls, thus effecting a saving of construction expense; the substitution of concrete for steel resulted in halving the cost of the vats. The material has given complete satisfaction; the plant is in successful operation, and detailed results of actual practice will be awaited with interest.

Prospecting

The invitation, conveyed in our issue of April 23, to our friends the prospectors to 'chip in' with contributions to the discussion of this subject has been accepted by many of them in the most excellent spirit. We have published a number of letters. It will be noted that there is general agreement on two points: that the gambling in cheap mining stocks has diverted the money heretofore available for prospecting, and that the suspension of assessment work on mining claims has alienated a large part of the public domain that might invite exploration on the part of real prospectors. In our issue of May 21, Mr. W. K. Whitmore objects to the suspension of assessment work; a week later Mr. Francis O'Boyle makes the same 'kick'; so does Mr. E. C. Watson. We agree with them; the urge for excusing locators from doing work on their claims comes not from the genuine prospectors, who want to explore, but from those who desire to hold claims while their neighbors prove the character and extension of the veins or lodes in immediately adjacent ground and thereby give some sort of value, fictitious or real, to their locations.

The other conclusion, that prospecting suffers from wild-cat promotions and the gambling in cheap stocks, finds even stronger support. The "fake mining companies", as Mr. E. M. West calls them, absorb the money that the local storekeepers and others used to put into grubstakes; the public, even in the vicinity of mines, prefers to dabble in 10-cent shares rather than to subscribe the working capital that is needed for a small mining adventure led by a reliable prospector of the old-fashioned type. Mr. F. W. Wright asserts that the former backers of the prospector are taking longer chances of buying stock on a margin, in preference to backing the real search for ore. With this view likewise we are in sympathy; too many people regard mines merely as counters in a gamble; they seem to think that 'mining' consists in digging into the pockets of other people, and that 'milling' is the concentration of currency from the pockets of the many into the coffers of the few. Mining is the making of money by the exploitation of ore deposits; it is not the deception of simpletons or the trapping of the unwary. The stock-exchanges have a function to perform, of course, but an enormous amount of capital and of human effort is wasted on them; we do not blame the genuine prospector for feeling sore that he is neglected while the wild-cat promoter wins such frenzied support. A great economic waste is apparent, and all the talk about the need for exciting public interest in the mining 'game', as a means for raising the money expended in actual mining operations, will not obscure this fact, to which our friends the prospectors point, not without bitterness. Undoubtedly if only a small part of the money that the public spends on Bush street, on State street, or on Wall street, were made available for systematic and intelligent exploration in the mountains and deserts of the West, there would be found much new ground upon which profitable mining could be conducted. We agree with Mr. William Crocker that there is a lamentable waste of money and labor in assessment work; much of it is done without any idea of its proving useful; it is perfunctory and is done to meet the legal requirement. Mr. S. L. Perini suggests the organization of a prospectors' bureau, for the purpose of giving technical and other advice to the men in the field. We venture to suggest that if the annual dues on a location were payable, at the owner's option, in cash instead of supposed work, it might be practicable to collect a large sum of money for the purpose of assisting prospecting by means of a bureau of information, or by building roads, providing ore-testing facilities, or doing other things directly helpful to those engaged in prospecting. The genuine prospector might still prefer to do his assessment work by personal labor; but others, not miners, might be permitted to pay a part or all of the \$100 to a fund such as we have indicated. Thus a large reserve of capital would be accumulated for the purpose of stimulating the search for new ore deposits. At present millions of dollars are frittered away or simply wasted in nominal labor without any real purpose and of no actual usefulness.

Some direct contributions of information on the art

of prospecting have been made. Mr. Crocker outlines a plan of action and gives sundry useful hints, based upon his personal experience in Central Africa and elsewhere. Mr. S. A. Knapp describes the methods he found successful in Nevada. His plan of 'pocket hunting', as he says, is an extension of the old Cornish practice of 'costeaning', and his description constitutes a real gain to the literature of the subject. As for the prejudice expressed by sundry prospectors against the mining engineer, we understand it, just as we understand the similar prejudice of many mining engineers against a certain type of prospector. There are small-minded men in both professions, for a genuine prospector is a professional man no less than the engineer. The best of those engaged in either calling have a high regard for the other, based upon mutual understanding and appreciation of the work each performs. This leads to intelligent co-operation, which, of course, is what is needed for the extension of profitable mining activity. Such discussions as the one we are reviewing will help to promote the goodwill and sympathy that are needed for the promotion of the best interests of the mining industry.

Professional Advice From the Bureau of Mines

Our Eastern contemporary, the 'Engineering and Mining Journal', draws attention to a report that was recently published by the Bureau of Mines, written by a Bureau metallurgist, and dealing with the treatment of goldbearing tailing from an Alaskan mill. Objection is made by the 'Journal' that the Bureau has committed a breach of etiquette in failing to observe the recognized line of demarcation between its own legitimate activities and those of a professional practising engineer. The rebuke is pertinent and timely; but we do not agree entirely with the tenor of the criticism. "The report", it is said, "is suspiciously like many we have seen over the signatures of practising metallurgists . . . we feel that the Bureau is treading on dangerous ground both in carrying out testing work which is distinctly an encroachment upon professional practice and in spreading a report which might lead others to believe that the Bureau's research work has descended into the category of the side room of the assayer's shop." An unhappy comparison is suggested between the work of practising engineers and the "Bureau's accomplishments in the broader fields of research". However undesirable and improper such a proceeding may be, we are disinclined to believe that the Bureau's labors would necessarily suffer a decrease in dignity if its officials were to encroach on the domain of the practising engineer. If the 'Journal' meant to say that the report under consideration was a joke, then we agree. It is to this phase of the question that we invite attention, in the hope of warning mine operators that, should they call in Bureau of Mines engineers for professional advice, they must not place too much reliance on the result.

The report was for the purpose of suggesting a suit-

able procedure to a company operating in Alaska that had treated a comparatively small quantity of oxidized gold ore by amalgamation. The tailing was available for experimentation. For some inexplicable reason no leaching tests seem to have been made on the mixed material. The report shows that 65½ pounds was taken for a concentration test, from which four products were obtained: concentrate, middling, sand, and slime. Only about 2½ pounds of concentrate resulted; but this fact did not deter the official from making a complete series of tests in bottles. Two pounds of cyanide per ton of solution and 10 pounds of lime per ton of tailing were used. The ratio of solution to ore is not mentioned. The result, after periods of agitation varying from three to five days, was that a "satisfactory extraction" was obtained from all the table products. The report states that the cyanidation of concentrate is only feasible on material obtained from oxidized ore, and that high extractions cannot be expected from a sulphide concentrate. This shows either an entire ignorance or an utter disregard of the literature on the subject. An outline of the proposed plant is then given. It is to consist of a concentrating table, two 40-ton leaching vats (each 16 by 5 feet), precipitating plant, sump-tank, centrifugal pump, and the necessary piping. The flow-sheet shows that the amalgamation tailing will pass over a table of the Wilfley type, yielding a concentrate, a sand, and a slime. A clean concentrate from a sulphide ore could be shipped, we are told; whereas the concentrate from an oxidized ore should be cyanided. The sand, which represents all the tailing except the slime, is to be leached with cyanide solution. The slime is sent to a pond, to be reserved for future treatment, or a concentrate is obtained by flotation. A total cost of \$1.80 per ton of sand treated is estimated; and it is anticipated that the capital invested would be returned after twelve months' operation, provided "the ore blocked out in the mine warrants the assumption that 3000 tons of \$40 ore can be mined and milled".

A practising engineer would detect several serious flaws in the Bureau engineer's work and conclusions. In the first place, the concentrate produced contained only 11.2% of the gold in 3.7% of the weight of the original tailing. The 'value' of the concentrate is given as \$22.48 per ton, as compared with a 'value' of \$7.21 per ton for the original tailing. The operator is told that if it comes from an oxidized ore it must be cyanided, but he is not told how to do it. According to the results obtained, only about 750 pounds of concentrate would be produced per 24 hours. If he is to re-grind it, then additional plant is necessary; if re-grinding is not to be advocated, then why the concentration in the first instance? A five-day cyanide treatment showed an extraction of 88.4% of the gold in the concentrate. No apparent justification exists for the isolation of this material, or for the expense involved in the purchase of concentrating equipment. The recommendations include the provision of two leaching vats, each of which would require six days to be filled. The rate of feed would be, we are told, 6.4 tons of sand per day, or about 500 pounds per hour. This amount would be delivered over an area of

about 200 square feet, by means of an automatic revolving distributor. We foresee difficulties in the uniform filling of a vat of such a size with so small a flow of pulp. We doubt whether it would be practicable, consistent with normal supervision. In any case, an abundant flow of water would be necessary, and this would lead to other complications. The maintenance of an adequate alkalinity in the mill-water, by the addition of lime, usually favors a satisfactory yield of gold from the plates; but no provision is made for the return of the mill-water, and a serious loss of lime is inevitable; or, as an alternative, there will be a reduced recovery of gold in the mill. The plant is arranged so that all the solution from the vats goes through the zinc-boxes. This is a mistake. Solutions low in gold and weak in cyanide, such as the last washes, should be passed direct to charges of ore in the earlier stages of treatment, the cyanide and alkali contents being adjusted as found necessary.

We question the wisdom of the general recommendations. We consider that work should have been concentrated on amalgamation treatment until a dump had been accumulated, of such a size and gold content as to justify adequate preliminary tests. The results of tests in bottles are often worse than useless; they are misleading. To subject goldbearing tailing and cyanide solution to a violent agitation in a bottle, and then to remove all the solution by repeated washings, is an experimental operation that cannot be duplicated in practice. As a basis for the recommendation of a leaching process, it is an absurd procedure. We consider that the advice of the Bureau of Mines that the operators should erect a cyanide plant of obviously inefficient design for the purpose of treating so small an amount as 6.4 tons per day is fundamentally wrong; we consider it stupid to disregard the cyanide treatment of all the slime, when it contains 40% of the total gold in the tailing; and we consider that flotation is not likely to give either a low residue, a good extraction, or an easily marketable product. The recommendation as to the flotation of the slime from an oxidized gold ore ignores all the work that has been done in small cyanide-leaching plants, where dividends have been paid as a result of the adoption of a method ensuring the thorough mixing of sand with as much slime as possible, and the treatment of the whole in a small, but properly designed and well-equipped unit. With flotation, a residue assay of 0.16 and 0.22 ounce of gold per ton is considered, by the Bureau engineer, as an encouraging result. To us it indicates a serious loss, if not the unsuitability of the process. Further, a product would be obtained, on the sale of which the small operator would stand a chance of being victimized. We regret the issuance of reports such as this by the Bureau of Mines. We agree with our contemporary in New York that the practice encroaches on the domain of professional metallurgists and assayers; we have been guilty of encroaching on this domain ourselves in an endeavor to show that the adoption of the Bureau's recommendations could do the small mine-owner no good. The report in question cost nothing; if the proposals suggested were adopted it is quite possible that it would prove to be worth even less.

DISCUSSION

Lead Salts in Cyanide Practice

The Editor:

Sir—Referring to your editorial article on 'Lead Salts and Plagiarism' in your issue of February 12, I should like to mention further earlier references to the use of lead salts in cyaniding:

1. Journal Chemical, Metallurgical & Mining Society of South Africa. Vol. III, p. 64 (Oct. 1902).

2. Do. Vol. VI, p. 326 (April 1906).

3. Do. Vol. VIII, p. 266 (March 1908).

4. Do. Vol. IX, p. 10 (July 1908).

5. 'Rand Metallurgical Practice', Chap. IX, p. 387 (1912).

The conclusions quoted by R. W. Perry in the same issue from Fahrenwald's 'Cyanide Process', and those which he has proved by his experimental work, are in the main indicated in the above references.

Johannesburg, April 13.

ANDREW KING.

Prospecting

The Editor:

Sir—Your very interesting address on this subject, delivered before the Portland Mining Convention recently, has aroused in me a desire to make a few comments, and, as I am a real prospector of over 25 years experience in the hills, I have no doubt you will agree that I ought to know a little about the subject.

In the first place, I could not help noticing that you too seem to be under the impression that the genuine prospector is disappearing from the hills, and we read and hear a great deal to the same effect from nearly every quarter, with amusing speculation as to the reasons why, which are quite simple, in my opinion.

I must differ from what appears to be the prevailing impression of what constitutes a genuine prospector, held by those who write on the subject in what they appear to be unable to disguise, a sort of condescending and patronizing tone, as if they were discussing some inferior unintelligent specimen of the *genus homo*, who in his sober moments is more or less of an amiable imbecile, and when not in the hills, is usually found staggering around under a load of Red-Eye whiskey with tobacco-juice dribbling slowly from the point of his chin while he importunes the local saloon-keeper to give him another grubstake, or is showing pocket specimens from his reputed latest find to all who will listen, and begging them to invest \$50 or \$100 or even less, in an interest, so that he can indulge in a little more Red-Eye; Red-Eye, of course, being the only

source of enjoyment for creatures of his calibre, when not wandering through the hills like lost souls. It seems to me that it is a fine thing for humanity if that type of prospector (?) has disappeared from the mountains. Let us hope he has also disappeared from the earth.

Now, my ideal of a "genuine prospector" is quite different, and there are plenty of him left, especially in the newer sections of this continent. He is a man of good strong physique, and just as venturesome and courageous today as prospectors ever were. He is an intelligent well-read man, and frequently well-educated. He does not find whiskey nor any other kind of booze necessary to his happiness, although he can and does take a drink if he feels that he needs it. He scorns to take a grubstake from anyone, figuring that his time and the knowledge he has acquired from books, and that best mining school of all, the School of Experience, are worth much more than the grub he will consume on a prospecting trip. While he hates to work for wages, he does so, when not prospecting or developing claims already located, so that he may be independent and not beholden to any man for the sinews of war. He is able to "size up a prospect", which, as you truly say, cannot be taught in any school of mining engineering.

There are plenty of such prospectors as above described in this section, and, as I have already said, in all the newer parts of the continent, but a great many of them have quit the prospecting game and gone into other lines, where the same qualities that made them good prospectors will be practically sure to make them independent in time, whereas they well know that even the best of prospectors must take his chance of winding up his career in the poorhouse.

The reasons why prospectors are quitting the profession of looking for mines (and it should and I believe yet will be raised to that dignity) are simple, and surely must be quite obvious to many engineers who write to the 'Press' and advocate this, that, and the other remedy for a condition which they have not, or pretend they have not correctly diagnosed.

The reasons most prospectors have quit are exactly the same reasons that cause any other business-man of sound sense to quit any other business in which he may be engaged, namely, inability to make prospecting pay, and the improbability of being able to make it pay during the lifetime of the present generation.

In your issue of January 22, 1921, there appears a letter written by me entitled, 'Ex-soldiers and Prospecting' in which occurs the following paragraph, which I think covers the ground in a very few words. The rea-

sons why prospecting is a poor 'spec' for returned soldiers or anyone else are, "Because there is no demand at present for any of the metals excepting gold, and even that, unless the prospector is lucky enough to find it as a shallow alluvial deposit or as an absolutely free-milling quartz deposit, so that he can make it productive by his own efforts, will not do him much good, for the simple reason that otherwise he will be left with a white elephant on his hands, like the thousands of other claim owners, many of whom have good likely-looking propositions near existing lines of transportation, which they are unable to work for themselves from lack of modern machinery or the means to buy it, and therefore must hold indefinitely or sell at their (the companies') figure to the mining companies that have the necessary capital and know it and take advantage accordingly, for every experienced mining man knows that hardly ever does a prospector who is fortunate enough to find a really good prospect, which soon develops into a mine, get enough for it to adequately repay him for the risks he has taken, the time and money he has spent, the disappointments he has endured, and the sacrifices he has made in order to find it."

That the above paragraph is a correct diagnosis of 'What is the matter with prospecting?' I challenge any or all of the engineers who took part in your symposium of 1914 to successfully deny, and, while it may be partly true, as they almost unanimously concluded, "that there was plenty of money for the development of promising prospects", it is absolutely true that the money spent for developing a promising prospect is not going to do the finder thereof much good unless he gets a fair share of its value after development. Rockefeller's income may be one hundred millions a year, but I fail to see that that interesting fact is going to benefit me unless I get some of it.

Those who claim that prospecting languishes because prospectors ask "outrageous prices" for claims are talking pure rubbish, for any claim that is really a prospect worth developing is not bought and sold nowadays for cash, but is generally taken under bond for development, and the prospector gets but little if any cash, until the bondholders have satisfied themselves at any rate that the prospect is a mine, and even then, as I have said before, the prospector's share is insignificant and not enough to keep good men in the game any longer than they can help.

If the prospector has certain psychological peculiarities, the mining engineer and investor have also their own funny little ways, as I have observed over and over again. For instance, a mining engineer will come into a new camp and look the prospects over, and select a third- or fourth-class prospect for development, because he can get a bond on it for two years with no cash down to the owner, and the ultimate price only \$20,000. The clever engineer thinks he is doing great business, and then proceeds to spend about \$100,000 or more looking for ore on his bargain (?). At the end of the two years he has a long hole in the ground, but no ore, and perhaps little prospect of finding any. He had previously looked at another prospect of the first class. That is a property on

which the owner had done sufficient intelligent development to show that his deposit had three of the four qualifications necessary in a mine, namely, length, breadth, and payable ore fairly evenly distributed, and it only required development to a comparatively trifling depth to prove it to be a valuable mine. Twenty thousand dollars expended in drift-tunneling on the ore would block out \$2,000,000 worth of ore, provided the deposit maintained its length, width, and value as it went down, but the "outrageous hog" (?) of an owner wanted \$100,000 if the property developed as it did in his own surface workings. Of course, the smart engineer thought such a sum far too much for any prospector, no matter what he had to sell, and turned him down with scorn and took the third-class, but cheap, prospect, which cost him \$120,000 for a worthless hole in the ground. If he had taken the first-class prospect he would have also spent \$120,000, but he would have had a valuable mine to show for it. The moral is obvious.

DONALD C. SIMPSON.

Smithers, B. C., May 10.

The Editor:

Sir—The address on this subject delivered before the International Convention at Portland, and appearing in your issue of April 23, I read with great interest and I must say I found it to be O. K. It covers the subject pretty well. You say you like to hear from the real prospector. Well, if I could write a nice article explaining the matter clearly, I certainly would send one for publication, but unfortunately, as you say, to me the pick is mightier than the pen, and the reason I am moved to write these few lines is to tell you just what I know about prospecting and why the good old prospectors have quit.

Now as to prospecting, such as looking for indications, signs, and anything that might lead to the discovery of ore, I couldn't suggest better methods than Mr. T. A. Rickard did. My idea in writing is to show the principal reason why the old prospector has quit his search on the lonesome mountain, no one taking his place. Present conditions are very unfavorable, not merely because the cream has been skimmed; I myself know that even here in our home State there is plenty of good prospecting ground, not only in the north-eastern part of it, but all the eastern slope of the Sierra Nevada is promising for big mines, but because the prospector can't sell his prospect any more, no matter how reasonable he is; he can't raise money and nobody will back him any more. The prospector's intention is to show up as much ore as he can and then sell out and look for more. Now, unless he hits real high-grade, so that he can ship it at profit, he is up against it. Why? One reason why, Mr. Rickard said, more new mines are not discovered is because the money for development is placed too frequently in the hands of ultra-conservative technical men who hesitate to incur the responsibility for which they have been retained. My experience in this game will prove this to be a straight fact. Now, don't get sore with me, you mining engineers, if I make this remark: that the mining engi-

neer is the worst enemy the prospector has got. The prospector with a prospect for sale hates to see the consulting mining engineer approaching his claim because he knows that if he is sent there by others to investigate or to examine the property, he will condemn it, sure. The engineer will turn it down, even when the property is pretty well developed and warrants a safe investment; he will take no chances; he's afraid to make a mistake and, in short, he is afraid of losing his job. Some people think the M. E. is an adventurous man. I guess just because he's managing and directing the mining industry, but we old prospectors know different. He is taking no more risk than a machine-shop mechanic.

Well, of course, business is business, and—safety first. However, I don't mean to say that the mining engineers are all alike. I think it would be wrong to say that. However, those that I have had anything to do with were just as I put it down here. In 1911 I was operating a lease and bond on a claim in Mono county. I had good ore in different places along the surface, but unfortunately it was quite irregular. There was not enough high-grade to ship, and no mill was available to treat the low-grade. I was at it for seven months. The beans and bacon was getting pretty low. One night I noticed an 'ad' in the 'Mining World'. "Gold prospect wanted. Write full description to Mr. Moneyed Man, Reno, Nevada". So the very same night I got up the description of my workings the best way I knew how, and sent it right off to Mr. Moneyed Man. Two days afterward I got a message from him to hold the ground, and an engineer would be out to see it immediately. After waiting several days and seeing nobody coming, I wrote to him asking what was the matter. He replied, saying he had found out from mining engineers that my ground was no good. Well, what can a man do?

I was positive that a big mine was in that hill, but I was approaching a time when something had to be done; I had to get somebody interested or let the ground go back to the farmers. So I put about 50 pounds of good ore in a sack and out I went to Reno with the intention of doing some business with somebody. Nothing doing. I had the ore about me, so I went up to see the Mr. Moneyed Man. I showed him the ore, but he didn't care to look at it: "My engineer," says he, "will be in shortly, he'll look at it." In a quarter of an hour before his man came in I remember he asked me this question 50 times: "Do you think there is a mine there, Mr. Perini?" "If I didn't think so I would never start to put in my own time on it," I told him. But that is not enough; it doesn't matter what you tell them. However, next day the engineer came out with me. I showed him everything and told him everything I knew about that particular locality. I saw that he was not sampling it right, but I did not say anything. Well, he returned to Reno. Three days after I got a message by wire, thus: "Regret your proposition is not suitable for our purpose." A few days after a man came along and offered me \$500. I took it and gave him an option. His company went right to work on it. They sunk a shaft 120 ft. and started cutting

the formation, and right under my coyote holes there was a nice little vein 14 feet wide assaying right across \$4067 per. This was one of the biggest bonanzas in quartz discovered in the world, but the world hardly ever knew anything about it, as the operators and company caved in that tunnel for four years and denied they had made a strike. I guess it was a freeze-out. Of course, the news spread out so fast that indirectly everybody in the country heard it. So, the first opportunity I got I called on Mr. Moneyed Man. I just wanted to tease him. Well, I said to him, "I guess the proposition would be suitable for your purpose now, wouldn't it, Mr. Miller?" He cursed the mining engineers some, but that didn't do him or me any good. Things of this sort occurred to me more than once, and it seems they happen to others. What we should have to encourage more prospecting is what I would call a prospector's bureau, run by a man who must be well qualified with technical and practical experience, a man like Mr. Rickard undoubtedly would fill the place. This bureau would serve as a place for the prospector to list his prospects with a description of same. The prospector should furnish a report and other data, telling just what he has. The person in charge of the bureau ought to be a good judge, able to tell if the prospector is sincere in his statement or not, able to find out why he wants to sell out, etc. This would give him an idea whether it was worth recommending or not. The bureau ought to be so largely advertised that everybody in the country would know what it was for. Then those desiring to speculate a little on a mining venture would know just where to go to get information. If we had something of this kind, the prospector would have something to fall back on, but the way it is now is disappointing. However, I have got to stay with it. I may get a streak of good luck yet; at any event, soon I'll be out in the mountain taking a chance once more. If I hit it rich I'll let you know.

Santa Barbara, California, April 25. S. L. PERINI.

Origin of Spanish Names

The Editor:

Sir—In your issue of March 12 you explain the origin of some Spanish names in the American South-West. I think you go too far in your guess as to the meaning of 'Arizona'. The discoverers of that dry land, thirsty after their ride, certainly exclaimed many a time that it was "*arida zona*" or 'arid zone', from which Arizona soon became the common name, and that explanation is good enough to any one born to the Spanish language.

These contractions are very common in Spanish. I have been amused at Americans who speak good Spanish being puzzled at the word *pundonor*, which is simply a contraction from *punto de honor* or "point of honor".

I believe California is a name similar to that of Arizona. The discoverers must have found Lower California 'as hot as a furnace', and since 'f' and 'h' were then so interchangeable, somebody invented the expression *caliente forno*, from which California was soon contracted.

You have another case like that in 'Cape Horn'; Magellan named the extreme end of South America *Tierra del Fuego*, from the fires that the natives lit near the shore, and, of course, the Cape was named *Cabo de Hornos*, or 'Cape of the Furnaces'. English mariners looking at the early charts very soon aspirated the 'h' and you get 'Cape Horn', but a horn is not a furnace.

The word 'sherry' is the nearest your English forefathers could come to pronounce the old Spanish name Xerez or Jerez, as the wine is now called. They started calling it 'sherez', and soon came the present name 'sherry'.

I am always distracted when I see people writing about the "Ladrone Islands". They do not know that *ladron* (thief) takes 'es' to make the plural, since a consonant cannot take a simple 's' for the sake of euphony. A word ending in a vowel adds an 's', like *padre*, *padres*, but *mujer* makes *mujer-es* and *ladron*, *ladron-es*.

Mexico City, April 14.

VICTOR M. BRASCHL.

Russian Placer Mining

The Editor:

Sir—Your issue of April 30 contained a letter written by Mr. G. L. Holmes in which he sets forth very plainly the erroneous conclusions of Mr. Leon Perret regarding the advantages of steam-driven gold dredges over those of the electrically driven class. Mr. Holmes' many years of experience in gold dredging enables him to draw correct conclusions. These conclusions will be substantiated by almost anyone who has a thorough knowledge of the subject.

The difficulty with Mr. Perret's conclusions is due to a serious error in his figures as set forth in his first article published in your issue of March 19. In the closing paragraph he states that the power-plant of the Kolchan mines is using from 26,000 to 40,000 cords of wood per operating season. In these figures Mr. Perret was careless in adding one too many naughts at the end.

The consumption of fuel at the Kolchan power-plant, according to the official reports of the company, has averaged 3500 cords of wood per season, and not 40,000. The Orsk company's Kolchan 7-ft. dredge in the season of 1915 operated 218 days and dug 628,762 cubic yards, whereas the average of six dredges having the same size buckets as the Kolchan dredge and belonging to the Demidoff Estate, according to the figures published in your issue of May 30, 1914, averaged 376,200 yards per dredge for a season of 256 days.

The Demidoff dredges are of the well-known steam-driven type for which Mr. Perret claims great superiority, while the Kolchan dredge was built by the New York Engineering Co. and at the time represented the best in American mining equipment. This dredge, which operated 38 days less than the Demidoff dredges, handled nearly 75% more gravel; moreover, the Kolchan dredge during the time produced gold to the value of 656,299 rubles. The working cost, including the winter upkeep,

was 112,487 rubles. This showed a net operating profit of 546,815 rubles, or \$271,907, which was about the original cost of the dredge installed and operating. The above figures are taken from the official report of the company.

In Mr. Perret's first article, in your issue of March 19, he states that the Orsk Goldfields yielded no profit during the first nine years of its operation, regardless of the fact that American mechanical methods were adopted. This is hardly a fair representation of the facts, as the two dredges made very handsome money during these years, but were not able to pay dividends on about \$3,000,000, which was included in their capitalization and which had been previously lost in a lode-mine operation some years before the Orsk dredges were installed. It was no fault of American mechanical methods that these two dredges were unable to earn dividends on capital sunk in another enterprise.

The above facts are well known by most everyone familiar with Russian mining enterprises and when one loads American mechanical methods down with such a burden as set forth above, together with 40,000 cords of wood per year for fuel consumption, it is no wonder he is able to make out a good case against American mining methods.

A. C. LUDLUM.

New York, May 19.

Coloring of Glass

The Editor:

Sir—In 1910, I found in the vicinity of Searles Lake, San Bernardino county, the remnants of a broken glass bottle. The color of the glass was violet. The bottle had been, to all appearance, an ordinary medicine one of colorless glass. As the color interested me I broke off the jagged edges from the neck portion and took it home. Some time after I showed it to a friend, who stated that it was a common property of colorless glass to become tinted violet on long exposure, and that in Boston, Massachusetts, some of the residents were very proud of their old violet-colored windows.

In 1913, in Rhodesia, South Africa, I found on top of a granite boss, the remains of a whisky bottle. I knew it to be a whisky bottle because a bit of the label still remained. The bottle had been colorless, because that brand of whisky was put up in colorless bottles. The broken bits were violet-colored.

Has anyone else noticed this and is it known what takes place in the glass? Both of my finds were in places subject to intense and prolonged sunshine.

London, April 24.

FRANCIS DRAKE.

[We are glad to hear from Mr. Drake, and confirm his observation. Most of our prospecting friends would see pink if they found a bottle of whisky, and if it proved the empty shell of a fervent hope they would see blue, not only the glass, but sagebrush and pine as well.—EDITOR.]

THE CARSON HILL MINE AND MILL AT MELONES

Mining on the Mother Lode of California

By A. E. Rau Roesler

The history of gold mining in the past twenty or thirty years has played a very secondary part in the economic development of the country. The expansion of our foreign trade and the position assumed by the United States as a creditor nation has made it possible for the Treasury to maintain so huge a gold reserve that domestic production of gold has become unimportant. This has reflected to the serious detriment of the areas of production, notably the Mother Lode region of California, which is probably the most important source of gold in the United States.

There are today perhaps a thousand patented mining properties in the area called the Mother Lode, and probably three times that many unpatented claims. The production to date is estimated variously at from a billion and a quarter to a billion and a half dollars. The population has decreased tremendously in the past ten years. There are in excess of one hundred idle plants in the region. With the exception of a few prominent mines, all the former producers are closed.

However, there is a curious connection between general industry and gold mining—an underlying relationship that affects the business of gold mining when economic conditions in the country generally become depressed. This is again making itself felt along the Lode and will probably result in permanent gain to the mining of gold.

In business circles it is axiomatic that industrial depression means loss of exports, bringing a closer balance between export and import; the foreign sources of gold become less available and the country turns to its own resources in gold. A time of deep depression and the closing of factories, with idleness among workers, brings an increasing activity in gold mining. Copper, iron,

and the minor minerals used in manufacture suffer with the general commercial business, but gold reacts in an exactly opposite direction. This, then, is a logical time to bring to the notice of the mining world the importance of the area generally known as the Mother Lode of California. It has been measured, mapped, and described, but there has been no work of a technical nature done on the Lode since the time of Ransome and the folios completed in April 1899. The works available are incomplete, incorrect, and not dependable.

An instance is afforded by the Angels Camp district, lying between the Stanislaus river and San Andreas. Mineralogically, geologically, and petrologically it is a separate province, related only geologically to the southern and northern districts of the Lode. Credited with a production of some sixty to seventy millions of dollars in gold, no attempt has been made to either classify or name the form in which the ores occur. To the north and south the deposits are in the form of lodes, or leads, and veins; but in the Angels Camp district gold occurs in a majority of cases in pyritic deposits in the country-rock adjoining great 'bull' quartz veins, and not in the quartz leads or lodes. The mineralogy of the deposits is different from that of the northern and southern areas; the metallurgy as practised suffers from inherited ailments, from methods imported into the district from other localities along the Lode. Because stamp-mills, re-grinders, plates, and concentrators are good practice in the north or south, on the free-milling quartz veins, the sulphide bodies of the Angels Camp district undergo the same treatment, when probably rough grinding, concentration, and cyanidation would be sufficient to extract all the metal made available through the intricate processes used in the

treatment of gold ores containing free gold, and warranting amalgamation. Of course, there must be a stamp-mill; no property in California is complete without one, when the ore to be treated is a gold ore, even though the gangue in which the metal lies is a soft and fissile schist, which comminutes so rapidly that it often clogs the stamps, and requires enormous amounts of water to carry it through the screens. Of course, even in the present practice, cyanidation is used on the tailing and in the recovery of gold from the concentrate.

Geologically the area consists of a series, not one or two, but a series of parallel deposits, separated by a width of over two miles between the eastern and western ore-zones. At Carson Hill there are five of these zones, close together and separated by narrow widths of wall-rock. At Altaville, and the northern part of Angels Camp, there are four to six zones covering a width of two miles. Lying west of these zones and paralleling them is an entirely distinct belt, of an entirely different mineralogical nature, now coming into prominence through the operations of a few mines, that have found in this particular belt a new field for development.

The ore occurrence, the topography, and the mineralogy of the district, as it really is, does not appear in the Geologic folios, nor is the topography correct, so that in using the sheets it is often confusing to find the streams running uphill.

There are many reasons why there are so few producing mines on the Lode today, the principal one being, of course, the advanced cost of materials. Labor has been scarce, but there has never been a marked increase in the cost of labor. Mining is in its third generation on the Lode, and the miners have been born and raised in the district. Besides this there is always, in times of industrial depression, a marked migration of skilled labor to the mining camps. The pay is comparatively good when living conditions are taken into account. Some of the great mines were operating on very low-grade ore when the War began. These were forced to close. But during the same period the Morgan mine, closed for many years past, was opened and now heads the list of productive properties. The Melones mine, closed because of low-grade ore, has been re-opened by the Morgan management and is operating on higher-grade ore than it has known for years. The deep mines at Jackson, the Argonaut and Kennedy, were closed on account of a fire underground, but are to resume production shortly. Every great mine on the Lode today has had its period of inactivity, due either to legal troubles, or to the fact that it was thought that the mine had been bottomed. With as good ore as has ever been found in the mine at 4900 ft. the Argonaut is a refutation of the theory that the ore, on the Lode, gives out, anywhere from the 1200 to the 1800-ft. level. The same is true of the Plymouth and the Kennedy.

After seven years of experience on the Lode, I have come to the conclusion that the closing of the mines is due, in a certain measure, to a failure in technical methods. Then, too, it may be added that the near field is

not green enough, and the very nearness of the Lode militates against it. Two great schools of mining and geology are maintained within easy seven hours run from the Lode. No geological work of importance, however, has been attempted since Ransome finished the folios. The general run of mining engineer seems to fear for his reputation when it comes to examining a once-closed mine on the Lode, and reports adversely after the most cursory of examinations. And yet the history of the Lode, the proved depth of the ore-shoots, and the

UNDERGROUND IN THE CLIO VINDICATOR MINE

enviable history of the newly opened mines should warrant much exploratory work and the investment of considerable capital. The closed mines, however, should be treated more from the geological standpoint than from that of the mining engineer. They should be treated rather as prospects than as mines.

Perhaps the results of the visits of examining engineers, of nomadic geologists, who can run over and condemn a district extending from Jintown to Angels Camp in 24 hours, has much to do with the present attitude of operators and miners toward technical help. Hellman's report on the Morgan mine is quoted freely since the mine has resumed operation, as a criterion of the knowledge that the average engineer has of real conditions on the Lode. Two of the most important mines in the region are operated by men without technical training and without a technical staff. Probably the owners and

operators have the same ideas that are prevalent on the Lode, that no lode mine can be operated as it should be unless the superintendent is born and bred on the Lode, nor is it possible for one who has not lived continuously on the Lode from childhood to acquire the knowledge necessary for the operation of a Lode property. It does not matter where one is born, whether on the northern, southern, or central part of the region, and although the ore-occurrence in the various areas made be entirely different, the fact that one is indigenous to the Lode appears to be the only necessary qualification for successful mining in this region.

There is a reason for all this, and it is not hard to seek. The Lode is the most available area of its magnitude and possibilities in the United States, or, for that matter in the world; it has suffered greatly from lack of development capital and the shortsightedness of operators; it has become the stamping-ground of the small promoter. Every prospectus of a Mother Lode mine has appended a terrific list of former producers, each with a guessed production of from a million to ten million dollars or more. Where large capital is wary, small capital anxious to become large capital will 'take a chance'. The result is inevitable failure, unless the promoter is more than usually active and successful, and knows his own limitations as a superintendent or as a manager. The supervision or superintendence is, with few exceptions, very mediocre. Technical help is useful in making reports, but the fact of the matter is that usually these reports are made in such a manner that the facts need not be faced, and the facts are that the Lode is a field requiring large amounts of capital, for the successful mine requires depth for a prolonged life, and there are everywhere zones of from a few hundred to four hundred feet in depth that are practically barren. Given sufficient funds to keep development ahead 500 ft. in depth, few mines need close down. That is history.

This may all seem like very harsh criticism, but it is brought out because there is a remedy. The potential qualifications of the Lode, the nearness to markets, the accessibility of the region, cannot be duplicated in any other gold-mining country. No other area is as little known as the Mother Lode, and none as poorly described. It offers a vast and profitable field for constructive geological and metallurgical work. An effort should be made for a re-survey, both topographical and geological, of the entire region, and with this as a basis the careful study and classification of the various mineralogical provinces would inevitably overcome the prejudices that today hedge the Lode from the necessary assistance that only capital and technical knowledge can supply to place it where it belongs: at the head of the gold-producing areas of the world.

DEPOSITS of high-grade bauxite have been discovered recently by the Gold Coast Geological Survey at and near the summit of Mt. Ejuanema on the Kwahu plateau, Gold Coast Colony, West Africa, according to an Imperial Mineral Resources Bureau bulletin. The summit of the hill is about 2300 ft. above sea-level.

An Old Story

Many momentous changes have taken place in the policy of Rhodesian mining enterprises in the past few years, and, generally speaking, these changes have been for the better. Fewer 'wild-cat' ventures are floated, although it can hardly be said that Charterland is altogether free of this species of the carnivore of mining. Years ago a chairman of a Rhodesian gold-mining company, speaking at an annual meeting in far-away London, made a most optimistic statement concerning the prospects of the particular proposition in which the gentlemen assembled were fortunate enough to be shareholders. He spoke of the millions of pounds contained in the ore-reserves 'in sight'. He drew a dazzling picture of the dividend aspect of the company, and to give his optimism a concrete basis of fact, he exhibited a specimen from the mine; a specimen containing considerably more yellow metal than quartz. The shareholders, who were mostly estimable old army gentlemen and well-to-do landowners, gazed upon this jeweler's-shop exhibit with intense satisfaction. "Gentlemen," continued the chairman, with the usual flow of a board-room's unctuous eloquence, "I am sure you will agree with me that it is a matter for congratulation that we have been able to acquire a 20-stamp battery on very reasonable terms. This equipment, gentlemen, has now been erected, and I am hourly expecting a cable from our manager in Africa, stating that crushing operations have commenced." The chairman paused, removed his gold-rimmed pince-nez, placed the specimen, with which he had been toying, on the table, and beamed benevolently upon the shareholders as a messenger-boy handed a cablegram to the secretary. The secretary, in turn, handed the fateful document to the chairman, who thereupon read it aloud to the meeting, in response to the unanimous wish of the shareholders. And this is what the cablegram from the manager stated: "Your instructions *re* crushing noted. Erection mill completed. Cannot commence crushing until you return the mine". And the venerable gentlemen thereupon gazed upon one another in amazement. They were not miners and they did not understand. But a certain old squire, more quick-witted than the rest of them, solved the ironical enigma: "That's all there is of the mine—there on the table!" he ejaculated, and he was quite right too. This little anecdote is recited merely to indicate the sort of thing that has happened in the mining history of Matabeleland and Mashonaland—the tale is not recounted with any intent to convey the impression that such incidents are common nowadays.—From the 'S. A. Mining & Engineering Journal'.

GOLD DREDGING continues to hold an important place in Alaskan placer mining, states a U. S. Geological Survey report. In 1919 there were 28 dredges in operation for the whole part of the season, and they produced gold to the value of about \$1,360,000, compared with \$1,425,000 worth of gold produced by 28 dredges in 1918, eight in the Fairbanks, Iditarod, Birch Creek, and Mount McKinley districts, and 22 on Seward peninsula.

Cyanide Notes

By Algernon Del Mar

Although this paper is more particularly devoted to the apparent regeneration of cyanide during zinc-dust precipitation in a particular mill, the detailed description of the precipitation combination with suggestions for improvements may be of more than passing interest. Before approaching the main argument, I shall quote briefly from several authorities, but I shall not touch upon cyanide regeneration by means of chemicals other than lime as generally used for settling or neutralizing acid radicals, nor shall I discuss cyanide regeneration using aluminum as a precipitant, except to quote a line or two from Clennell.

Looking over the authorities available in a library of major size, I came to the conclusion that the subject of cyanide regeneration has received but slight attention; it has been noted only in a few instances, and no theory has been advanced to account for the apparent gain of cyanide when the metalliferous contents of the solution have been precipitated by zinc. The subject becomes of importance when we consider that in some cyanide plants solutions are allowed to circulate as solvents when they could be more directly precipitated. The question then is this, if there be a regeneration of cyanide due to precipitation by zinc, does that regeneration bear any relation to the amount of metal in solution, or will the total amount of regeneration be increased by passing the solutions more frequently through the precipitation process. The data at my disposal are not sufficient to answer these questions satisfactorily, but they indicate a line of investigation that can be followed with profit and interest.

In Wilson's 'Cyanide Process', quoting from Bosqui, we find the statement that by frequent tests it was found that there was not "the slightest difference in quantity between the cyanide present in an ingoing and an outgoing solution from the same boxes". MacFarren, in his 'Text Book of Cyanide Practice', says, "There is an apparent regeneration of free cyanide taking place in the zinc-boxes, shown by titrating the solution entering and leaving the boxes. This may amount to as much as a quarter to a third of a pound of cyanide per ton of solution. The exact cause is indeterminate". In a description of the Minas del Tajo mill, in Sinaloa, Mexico, we find that during a period of eight months there was an apparent increase in strength of cyanide "in the high-grade solutions from 3.280 to 3.560 lb., or approximately 8%, and of the low-grade solutions from 2.640 to 2.740 lb. per ton of solution, or approximately 3%. Drip-samples, taken at the head and foot of the boxes, have shown a regeneration of cyanide for a period of two years, due to the lime present, forming zinc hydrate and liberating cyanide".*

This shows a greater amount of regeneration in the richer solutions than in the poorer solutions, due no doubt to the breaking up of a greater amount of the double cyanides of the metals precipitated. Clennell, in his 'Cyanide Handbook', says that "regeneration of cyanide at the Nipissing aluminum precipitation plant amounts to from 0.64 to 0.72 lb. cyanide per ton of solution, and in addition to this the loss by direct action of cyanide on the metal, which occurs in the case of zinc, is avoided by the use of aluminum".

The mill at which my observations were made is in Sonora, Mexico. The ore is a brecciated feldspar filled with calcite and the prevailing economic mineral is argentite, finely disseminated, the average tenor being 8 oz. of silver per ton of ore. The crushing is done by stamps, followed by grinding in tube-mills, dewatering in Dorr thickeners, agitation in Pachucas, and washing on Oliver filters. The solutions precipitated are from the Oliver filters and from the decanted Pachucas. The overflow from the Dorr thickeners, which follow the tube-mill classifiers, is pumped to a tank to be used in the stamp-batteries. Solutions are titrated three or four times per shift and the average for the day is entered in the daily and monthly reports. Potassium iodide is used as an indicator for strength in cyanide and this same titrated solution is again titrated for lime with sulphuric-acid solution. The precipitation is effected with zinc-dust in pipes leading to a Merrill filter-press and in the press itself. This is a 36-in. press with 24 leaves in which ordinary building paper and *manta* are used for filtering. Newspaper was tried with some success, but the building-paper is slightly more porous and filters quicker.

The present management claims that chemically no lime is needed to better the extraction, but only sufficient need be used for settling the slime and that the higher the lime content of the solution the greater the consumption of cyanide. A former mill-superintendent contended that "a high protective alkalinity was necessary with this ore in order to keep down the quantity of zinc in solution". He then goes on to say that "owing to precipitation of basic zinc carbonate, the cyanide increases as the zinc decreases". Therefore the high protective alkalinity keeps down the zinc and the cyanide strength augments, a direct contradiction of the present method of cyanidation. This is only a side issue; my main purpose is to show the results of titrating the solutions before and after precipitation. Taking a representative month, there was calculated to have been precipitated 3000 tons of solution that titrated 0.68 lb. cyanide per ton before precipitation and 1.0 lb. after precipitation. This represents a regeneration of 960 lb. of cyanide during the month. The consumption of cyanide

*Trans. A. I. M. E., 1910.

was 1.38 lb. per ton of ore and the regenerated cyanide represented 0.32 lb. per ton of ore treated. In another month, when the consumption of cyanide was 1.42 lb. per ton of ore treated, the cyanide strength had increased from 0.80 to 1.08, a gain of 373 lb. of cyanide, or 0.28 lb. cyanide per ton of ore treated. The average lime content at all times was 0.14 lb. per ton of solution. The accompanying graph, Fig. 1, shows the titrations for 12 representative days, from which we gather that whenever the cyanide strength increased before precipitation there was a corresponding increase after precipitation or the increase may be taken as constant. As the variation in the metallic content of the unprecipitated solution was fairly constant, we have no means of determining whether the regeneration was greater the richer the so-

FIG. 1

lution. Owing to causes to be explained later the amount of metal actually precipitated per ton of solution varied considerably, but the regeneration did not follow this condition; it appeared to be independent of the actual amount of precious metal precipitated. This ore contained a small amount of oxidized copper, which may account for the fact that the regeneration of cyanide did not follow the amount of gold and silver precipitated, for the amount of gold and silver did not represent all the precipitation, the bullion containing 8% copper. I have never noted in a zinc-shaving precipitation plant the amount of cyanide regeneration as shown above.

In the month represented by the 1.38 lb. cyanide consumption per ton of ore treated an endeavor was made to precipitate as much as possible of the Dorr-tank overflow, which had always been pumped to the battery-solution vat, but, owing to causes not necessary to state here, this was not done to any great extent, but what little was done in this direction showed a gain, which indicated that a saving in cyanide could be effected by precipitating the solutions from the Dorr tank as well as from the Pachucas and Oliver filters.

A zinc-dust precipitating system should embody certain features to be successful, chief among these being:

1. The zinc-dust must be kept from contact with air.
2. The dust should not be allowed to form lumps.
3. The distance from the zinc intake to the filter-press should be short.
4. The filter-press should always be kept full of solution.
5. An automatic means of feeding the right amount of zinc for complete precipitation, but with no excess of zinc.
6. A means of measuring the amount of solution precipitated.
7. The solutions precipitated should be regularly titrated and assayed.

Fig. 2 illustrates a zinc-dust equipment, not to scale nor drawn with details. Each one of the seven features referred to above will be taken up seriatim in reference to this sketch.

Probably the least amount of air comes in contact with zinc-dust when the original receptacle is used. If this be the usual 100-lb. can, all that is necessary is to unscrew the cap, turn the can upside down on the feeder, and punch a small hole in the top. The zinc will now feed from the bottom and the only air exposure will be a layer on the top of the can.

Various devices have been used for keeping the zinc-dust from forming lumps, but a little ball-mill made from a 6-in. pipe running on roller-bearings answers the requirements. The stream of zinc-dust from the feeder, which may be of the Challenge type, or the screw-conveyor type, is washed into the ball-mill with a stream of water or solution, preferably the latter, as there might be a tendency for the water to oxidize the zinc.

As zinc-dust precipitates the precious metals almost instantaneously, pipes from the zinc-dust intake to the filter-press become encrusted with precipitate and soon little or no solution will flow through them. In some plants the pipes must be cleaned every two weeks, so it is well to provide pipes of large diameter. While the zinc-feeder and the filter should not be at any great distance apart, it is well to have the filter at a lower level, so that the solutions can flow to the press by gravity when the pump is not working. Some operators contend that a long pipe-line is an advantage by giving the zinc-dust longer contact with the solution, and if such should be the case the pipes should be washed on the inside with some paint to which the precipitate will not easily adhere.

When precipitating cyanide solutions with zinc, whether with zinc-shaving or zinc-dust, the zinc must be kept from contact with air, otherwise rapid oxidation takes place and the zinc is rendered unfit for precipitation. If a zinc-dust filter is allowed to become alternately full of solution and then dry, the precipitation will become very uncertain. An instance may be cited where the solution entering the press assayed \$3 per ton, the clarifying-vat had become clogged with slime so that the triplex pump was not only pumping solution into the filter-press, but likewise air. With a great excess of

zinc-dust the discharge solution assayed \$1.80 per ton, showing that when air entered the press, the precipitation was poor. There were two remedies for this condition, the first and best being to keep the standpipe that fed the pump full of solution or to allow the solution to run to the press by gravity without the aid of the pump; the second was to add carbonate of soda to the unprecipitated solution. Clennell says:† "In some cases the addition of sodium carbonate to the solution in the sumps has a beneficial effect, as it precipitates salts which might otherwise cause a deposit of insoluble carbonate in the boxes". I venture the explanation that zinc carbonate is not a deterrent to precipitation, whereas zinc oxide is, and that the sodium carbonate converted the zinc into carbonate in preference to oxide. As the condition causing poor precipitation may happen unawares, it is important to test frequently the precipitated solution, so as to head off poor precipitation as much as possible. This is usually done with sodium sulphide, the depth of

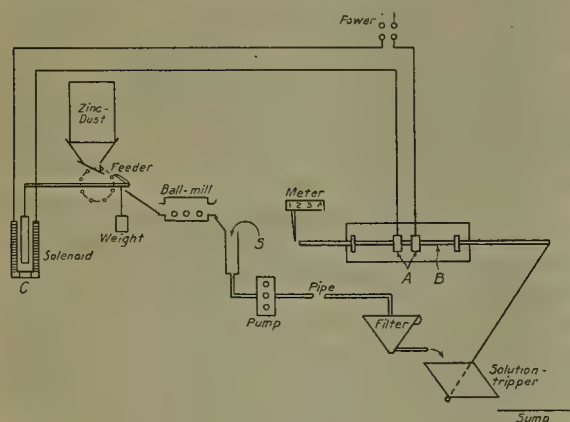

FIG. 2

the color indicating the extent of precipitation and giving a means of knowing when to increase or decrease the amount of zinc-dust. A permanent remedy for oxidation in the filter-press, and one that requires no attention, is to have the discharge from the filter higher than the press itself, so that the filter-press is always full. This has been done in a few mills, and the manufacturers should design the machine accordingly.

Referring to Fig 2, at C, we have a coil in which a magnet is hung. When an electric current passes through the wires at the poles of the coil the magnet is forced down into the coil. By attaching this magnet to a lever we have the means of actuating the feed-wheel of a small Challenge feeder, which feeds the zinc-dust into a standpipe connected with the force-pump. The electric current for this purpose at the Minas Nuevas, in Mexico, is taken from the electric-light circuit. Referring to the letters A and B, when A passes over the two insulated points B, a circuit from here to the coil is completed and the magnet is forced down, to be released when the connection A has broken the circuit,

so that the weight W on the lever pulls the magnet up. Every time the rod on which A is attached passes in the direction of the meter it registers that oscillation. The movement of this rod back and forth is caused by the solution-box tripping when over-balanced with solution from the discharge of the filter-press. Therefore, if we know how much the solution-box or tripper must hold to over-balance, we have a means of registering the amount of solution precipitated. As stated, every time the solution-box over-balances, the electric contact takes place and zinc-dust from the feeder enters the standpipe into which the unprecipitated solution comes, at S. If the metal in solution were constant and all other conditions were constant, once the zinc-dust feeder is set the operation would be automatic. Such conditions are not practicable, so the rate of feed of the zinc-dust must be varied from time to time and this variation is gauged by testing the precipitated solution with sodium sulphide, as is often done for testing zinc-box precipitation.

The solution-box for measuring the amount of solution precipitated when made as indicated in the sketch is not very accurate, because it does not always tip when the solution is at the same level. A better method is to have two receptacles of known capacity, one filling while the other is emptying. When the receptacle is full the discharge is opened and the stream deflected to the other at the same instant. A magnet and an electric connection will effect this operation as in the case of the zinc-feeder.

While it may be facetious to call attention to the fact that solutions should be frequently titrated and assayed, there are many cyanide plants in which one or the other or both of these operations are seldom performed. Particularly, tailing solutions are seldom titrated, but this is important if we would know how to run our plant to the best advantage, for regeneration of cyanide in zinc-boxes or filters is an important factor to be carefully investigated and made the most of. The particular question to be answered is whether this regeneration is dependent or independent of the quantity of metal precipitated and how the conditions favoring the maximum amount of cyanide regeneration can be brought about.

There is food for thought in the following statements quoted:

1. The regeneration is due to the lime present forming zinc hydrate, liberating cyanide.
2. The cyanide regeneration increases as the precipitation of basic zinc carbonate increases.
3. The addition of sodium carbonate in the sumps has a beneficial effect on precipitation.

It would appear that the precipitation of the zinc salts instead of the metal salts is the main cause of regeneration, which would account for the observation that when there was poor precipitation of the precious metallic contents there was the same regeneration.

THE output of asbestos from Rhodesia increased from 9799 tons, valued at £425,240, in 1919, to 18,823 tons, valued at £459,572, in 1920.

Mining Litigation and Common Sense

By Arthur B. Parsons

Judge Elmo E. Bollinger, of the Superior Court of Mohave county, Arizona, in his recent decision in the Tom Reed-United Eastern 'apex' suit, declared in no equivocal terms that, though highly interesting and illuminating, the theories advanced in the testimony of a dozen "eminent geologists and mining engineers" were of negligible value in assisting him to arrive at a conclusion on the issues involved. His Honor certainly ought to know whereof he speaks; the "eminent" gentlemen had devoted several weeks exclusively to the task of enlightening him with regard to the geological history of a small portion of the earth's crust in the vicinity of Kingman, featured by sundry faults, lodes, and ore deposits of great value. Their undivided efforts had been bent solely to his instruction. On the other hand, this same group of men and a number of others, variously classified as geologists, mining geologists, and court geologists, have become recognized generally as an essential cog in the delicate legal machinery that turns out high-grade decisions in disputes hinging on the capricious interpretation of the statutes regarding extralateral rights. When, then, Judge Bollinger frankly declares that they and their technical theories are no more necessary than the proverbial fifth wheel of a coach, such questions as the following immediately assert themselves: Have other judges simply tolerated them, listened politely to their instructive lectures, and then disregarded their scientific theories in favor of practical facts? Is it true that in nearly all litigation involving highly technical problems a large volume of non-essential facts, which dilute and obscure, can be boiled away, leaving as a residuum a simple practical question that the judge settles in his own mind by the aid of common 'horse' sense?

Such are the questions that have provoked the brief investigation that is presented in this article. The statement of definite conclusions has been studiously avoided; the reader may draw his own; then, if they fail to please him, he has no one to blame but himself. The inquiry includes a miscellaneous collection of evidence, some of which may be considered irrelevant and some of which is admittedly hearsay; sundry unanswered questions, of which some are pertinent and others are doubtless impertinent; and a few inferences, some of which may be logical, but none of which are guaranteed to be so. The reader is not only at liberty, but is urged, to season any statement with as much salt as he wishes.

Any individual whose services are in urgent demand at a per-diem remuneration of from \$200 to \$400, together with board and lodging in a salubrious climate like that of Butte, or Salt Lake City, or Kingman, is likely to acquire a measure of self-complacency verging upon

conceit. However, humility is recognized as one of the cardinal virtues, so that such a person should welcome for the good of his soul an occasional frank and detached estimate of the value of his wisdom from a friendly but unterrified critic like Judge Bollinger. The witnesses for the United Eastern side of the suit may seek to derive some small crumbs of comfort from the fact that the recent decision favored the company on whose payroll they happened to be, but they had better not flatter themselves that the Court placed any greater value on their profound geologic doctrines than it did on those of the geologists who advocated the cause of the Tom Reed company. The victors lay in the lap of Fortune. The Judge, after gracious acknowledgment of the "national and international reputations" of some of the "experts", observes that "a few practical miners also testified and furnished the Court with very valuable information because the problems involved in this case are largely practical ones"; apparently it would be presumptuous for United Eastern experts to insinuate themselves into the category of "practical miners" simply to share the glory of victory; they were lucky to be on the side of the practical miners whose views prevailed. By the same token the other well-known geologists who have participated in one or more of the many apex suits tried in recent years cannot hope to escape inclusion in the general indictment—if there be any—simply because they happened not to be engaged in the Tom Reed-United Eastern litigation. All stand or fall together.

The fact should be emphasized that it is entirely consistent to recognize and to appreciate the ability of these men and the value of their geologic learning as assisting in the solution of problems that confront the mine manager and in the advancement of the science of economic geology in our universities, and at the same time to question the value of their services, under the prevailing procedure in mining litigation, to the judge on whom rests the responsibility of deciding a law-suit. If, like the laws of Nature, the statutes made by man were perfect, if they could be depended upon to work with mathematical certainty, there would be neither law-suits nor lawyers. Every individual, by thoughtful study, could ascertain the outcome of litigation beforehand; the man on the losing side would settle out of court. Some are so unfeeling as to assert that lawyers frame the codes ambiguously and unintelligibly for the purpose, primarily, of promoting their own business. The fact that 80% of the seats in Congress and in most of our legislatures are filled by attorneys, coupled with the fact that the members of the multitudinous legal profession live in outrageous affluence, seems to lend a color of truth to the charge.

Whoever their authors and whatever the motives that brought them into being, the statutes exist; their effectiveness depends mainly on the good or bad administration of the courts. The law that accords extra-lateral rights to the holder of the apex of a vein or lode is one of the most practical and simple in its intent, but one of the most intricate in its application. In effect it says to the prospector and miner, "My purpose is to stimulate the search for ore; since you cannot see into the earth to learn which way the lode dips, I shall guarantee to you the right to mine the ore in the lode whose outcrop you possess, even though in following it you go beneath the surface of another man's claim". The principle is delightfully simple; on the other hand, the operation of Nature's laws has given the earth a crust that is decidedly complex. Disputes arose as to the meaning of 'lode', which is not specifically defined in the statutes; and of 'apex', which began to mean more than 'outcrop'. The courts were called upon to interpret the law and to decide the controversies; many decisions were handed down, and the list of precedents became lengthy. The quantity of ore found in a comparatively small vein, and the consequently large amount of money frequently involved, gave the legal battles a gradually increasing importance, and justified the expenditure of huge sums in preparing for, and in conducting, the trials.

Usually the judge knew little of mining and less of geology, so that specialists were employed by the contending parties to give 'expert' testimony, including opinions as well as actual evidence, to 'assist' the judge in his 'findings of fact', which, according to legal parlance, is then complemented by 'conclusions of law'. This 'assistance' necessarily was of two kinds, each having a radically different complexion. One assisted the Court to reach a decision in favor of the plaintiff; the other assisted him to decide for the defendant. Nevertheless the importance of expert testimony increased constantly, and it is an open question today whether the average expectant litigant would choose second-flight lawyers or second-flight geologists if he were obliged to forego the top-notchers in one profession or the other. Of course, this manifest esteem in which expert geological testimony is held by the mining companies does not prove that it is merited; the mining companies may be the victims of a prevailing error.

An insight into the usual methods of conducting a trial involving the law of apex may be gained from the following observations made by a well-known corporation attorney, who has won more important mining suits than he has lost. Nothing would be gained by giving his name, although the statements attributed to him were not made in confidence. His first point was the satisfaction he found in trying such cases before a judge instead of a jury; the training and temperament of the former tend to make him amenable to reason and logic. There is a trace of inconsistency, possibly, in the outline of the strategy the lawyer employs in launching his campaign against the citadel of the Court's judgment in the battle to gain the verdict. The case is studied

from every angle; a major phase of the dispute and perhaps a few minor ones are selected as being particularly strong points in favor of his contention and as being at the same time points most likely to impress the judge. Effort is then concentrated on these aspects of the suit. The maps and other exhibits are prepared so as to lay stress on particular points; much depends on the strategy exercised in coloring the maps. The emphasis gained by repetition is recognized. A hundred maps showing the same geologic fact with slight variations as it appears in each of 100 sections, parallel to one another and a few feet apart, will produce almost a hundred times greater impression on a judge, in spite of himself, than will a single map that adequately shows the essential conditions—or at least so the lawyers think, and they ought to know. Something of the same psychologic inference accounts for the engagement of half a dozen geologists instead of one, although here the aggregate weight of individual reputation is the most important consideration. Guided by the astute attorney as ring-master, these witnesses are put through their paces. They go by devious routes but they always manage to conclude by giving emphatic endorsement to the one fact that has been selected as the focus of effort; indeed, clever lawyers will manage to make each witness say the same thing in half a dozen ways, the better to accentuate the idea and to drive it home to the receptive auditor on the bench. It should be made clear that these are the self-confessed tactics of one good lawyer; there is no direct evidence at hand to implicate others.

But this is the offensive side of hostilities only. Every good general must have a defence. The opposing side has just as many exhibits and just as many witnesses, with college degrees and professional careers no less illustrious. Strangely enough, the things that the first side has indicated on its maps in a glaring shade of red that will not be denied, have been tinted a delicate blue or a dingy gray by the artists of the opposition. It would appear that they deem the outstanding features of geology depicted on the first set of exhibits as being of but little real importance, whereas on the other hand they have applied color lavishly to certain other geologic formations.

If it were not for the fact that there was virtual concurrence between the Tom Reed and the United Eastern advocates as to the structural and other geologic conditions in the ground in controversy, it might be suspected that Judge Bollinger had in mind two sets of exhibits when he remarked in his decision: "The Court realizes, by reason of former practice as a lawyer, that it is hard for counsel for respective parties to an action to see the law and the evidence in a given case, except through the glasses of the particular and favored color of his client, and, as partisans, lawyers are prone to pick out the different properly colored streaks of the law and the evidence; and, putting them together, urge that that particular combination is the real rainbow. . ."

But the most effective defensive maneuver is to confuse and befog the issue in those particulars wherein

advantage lies with the enemy. Testimony is given deliberately for no other reason than to bewilder the judge; the object is to stimulate doubt and uncertainty in his mind with respect to the dangerous contentions of one's opponents. This appears to be an imposition on the judge, but he is used to it; and "all's fair" in litigation.

'Court' geologists have been criticized because of the wide divergence of views expressed in the testimony of two opposing groups of witnesses. The question has been asked how six honorable engineers can testify as to a set of facts, only to be followed by six equally honorable and equally intelligent men whose views regarding the same facts seriously conflict with, if they do not flatly contradict, the sworn testimony of the others. With respect to contradiction of fact, this is invariably found in minor details; as to questions of interpretation, there may be honest difference of opinion. Generally, however, the apparent contrariety is a matter of degree, magnitude, or distinctness. The great truth that one of the litigants wishes to impress on the Court stands out on the mental horizon of his witnesses like the Woolworth building on New York's sky-line; it is a prominent, shining, clear-cut fact. The witness does not deny the existence of the vital facts championed by his opponents, but unconsciously he has so schooled himself that to his eyes they appear dwarfed and dingy, like a four-story loft-building on lower Broadway; he hedges them around with provisos and conditions, with limitations, evasions, and dubious admissions, hoping the Court will be unable to distinguish the unimpressive structure. His object is to leave with the judge a reproduction of his own mental picture that he has skilfully 'touched up' to emphasize certain features and to submerge others in a mass of non-essential and obscuring details.

It is a shrewd judge whose discernment is sharp enough to pierce the smoke-screen of technical geology, to sort out and discard the irrelevant from volumes of evidence, and to reserve the essential facts on which to base his decision. It is a wise judge who can sift the fact from the fancy, who is able to draw a sketch on the back of an envelope that depicts the real point at issue just as clearly as a few hundred handsome and expensive maps. Still, there is convincing evidence that some of our judges have done that very thing. A few examples may be cited.

The case of *Elm Orlu v. Butte & Superior* will be recalled. In the first suit the Elm Orlu, controlled by Senator W. A. Clark, had obtained, through a favorable decision by Judge Bourquin, possession of sundry ore-bodies underlying the Butte & Superior company's Black Rock claim by virtue of an established apex on Elm Orlu ground. It was contended that the Pyle and other so-called branch veins, which at this point on their strike were barren stringers and had never been mined, apexed in Elm Orlu ground; and that they carried with them ownership of ore in the combined vein below the point where they made junction with the Rainbow lode just above the Black Rock 1100-ft. level. The dip below the line of junction coincided more nearly with that of

the stringers than with that of the Rainbow above the junction. In preparation for the trying of the supplemental suit, ten raises from 500 to 1200 ft. long were driven and six miles of special drifts were run. The chief counsel for the plaintiff stated in court that \$500,000 had been spent by his side alone in doing this work. The models and maps were the most elaborate and costly ever prepared. The diagnosis of the unusually complex intersections and faults taxed the ability of the ablest geologists, and the trial was characterized by long and highly technical examinations and grilling cross-examinations.

After three weeks in court, during which 11 witnesses had been examined, it was announced suddenly that a settlement by stipulation had been made by the opposing counsel. By the terms of the stipulation the Butte & Superior relinquished 186 ft. of the Rainbow lode, from which the greater part of the ore above the 1900-ft. level had already been extracted, and paid \$2,500,000 in cash, although the actual profit netted by the Butte & Superior company by milling the ore taken from the disputed block had been estimated at from seven to eight million dollars.

However, the significant point is that on the day before the unexpected dénouement, Judge Bourquin had propounded to one of the witnesses a query to this effect: "If you had discovered this branch vein [referring to one of the Pyle veins] on the surface, would you have followed it for a thousand feet into the ground in the hope of getting ore?" This was an extremely practical question. It suggested the trend of the judge's thought. How much influence it had toward precipitating the settlement can only be surmised, but it is hard to believe that the sequence of events was purely accidental. Did one of the attorneys for Senator Clark suspect the incubation of an idea that he was afraid to let develop? Did someone interpret that plain question as indicating a tendency on the part of the judge to subordinate the intricate problems of vein-structure and relativity to the more practical one of what a miner would have done under the circumstances?

Apropos of this suit an interesting discussion took place as to whether it would be possible for any one of the expert witnesses to give just as effective testimony on the other side, providing that, at the beginning of his study of the problems involved, he had been searching for evidence to support the contrary view. One man pointed out that a witness usually knows little of the detailed geology of the mines when he is retained; and that, although provision is always made for withdrawal from the case in the event that the expert cannot conscientiously support the position taken, no such withdrawals are on record. The psychologist would point out that environment, the contact with other engineers, whose point of view naturally accorded with that of their clients, would necessarily have a strong influence in molding the theories of each individual. Another engineer suggested an experiment; even though the performance is impossible, the suggestion offers food for entertaining

speculation. He proposed that the minds of the ten experts be wiped clean of all facts relating to the history of the litigation and to the geology of the Black Rock and Elm Orlu mines, as a boy might sponge his slate. Each man would then make an entirely independent study of the geology of the two mines, the claim-maps, and the patents; then after as much deliberation as he wished, he would select the side for which he would prefer to be a witness. How closely would the new alignment resemble the old? Might all ten select the same side? Might the cleavage in the ranks of the contingent from Minneapolis disappear; might the Mills building and the Crocker building in San Francisco find themselves allied; or might it turn out that the shades of geologic theory propounded at Massachusetts 'Tech' would not square with those approved at the University of Wisconsin?

In the more recent suit involving mines at Bingham, Judge T. D. Johnson decreed that a thick limestone bed containing rich orebodies nearly 2000 ft. from each other, and separated by a quarter of a mile of practically unaltered limestone, could not be construed as being a lode entailing extra-lateral rights under the apex law. Accordingly, he found against the Utah Consolidated and in favor of the Utah Apex company. After reviewing in admirable fashion the testimony of the expert witnesses, and reciting his views of sundry decisions cited by the opposing counsel as valid precedent, the Judge, in the paragraphs immediately preceding his conclusions, says:

"The witnesses for the defendant testified that this intervening limestone was ground in which the miner might reasonably expect to find ore by driving or cross-cutting in any direction. As stated by counsel of the defendant in their brief, for more than 20 years this property has been operated by the defendant and its predecessors, during which time there has been taken from the mine ore to the value of 40 million dollars. Notwithstanding such immense resources the defendant has failed, except to the limited extent heretofore indicated, to prospect this limestone or develop it. I cannot escape the conviction that if there was reasonable expectation of finding ore by driving or cross-cutting in any direction in this limestone, the defendant, as a practical miner [note the word 'practical'] at the time it ran tunnels and drifts through this intervening limestone, or since, would have cross-cut the limestone, and that it would have extended some of the many short drifts and cross-cuts now terminating along the upper and lower edges of this undeveloped country."

Was not this the real crux of the problem? It requires little stretch of the imagination to believe that the Judge, with keen insight, perceived this simple fact to be the key to the adjudication of the controversy; having decided upon the verdict, he commenced the task of preparing his written opinion. He had at hand the two carefully prepared briefs, submitted by the opposing attorneys, each of which offered a plausible, adequate, and tenable interpretation of the law in light of the facts. The Judge merely selected the one that was in accord with the

conviction he had reached already and wrote his decision accordingly. The fact that this decision is considered to be something of a classic among similar documents, and that geologic problems are discussed in precise technical terms, does not indicate necessarily that the verdict is not based entirely on a simple question of practical common sense.

But to revert to the recent suit at Kingman. Judge Bollinger, in contrast to Judge Johnson, displays a woeeful lack of discernment in his use of geologic terms; indeed he occasionally takes such unjustifiable liberties with geologic fact as may well shock the sensibilities of a proper scientist. However, this is in connection with inconsequential points. So far as the essential facts are concerned, his perception seems to be keen and his exposition clear. For instance, in his dissertation on apexes in general, the verbiage may be described as amateurish, but the Judge knows what an apex is, notwithstanding. He does not presume to question the ability of the geologists nor the accuracy of their observations; he is convinced that their conclusions are sound. The issue has to do with the ownership, by virtue of extra-lateral right, of ore in the faulted portion of a vein that has its apex in the Grey Eagle claim owned by the Tom Reed company. This vein has been cut by two faults into three segments; the movement has thrown the lower segment upward, the main dislocation along the Mallery fault amounting to some 400 ft. The conditions are indicated in the accompanying sketch; the Big Jim claim is owned by the United Eastern company.

The Judge is satisfied with the evidence that establishes the identity of the faulted portions of the vein as having *once* been the lower extension of the main vein. He recognizes a horizontal displacement along the Mallery fault of several thousand feet and calls attention to the fact that therefore the ore deposit in the faulted segment could never have been physically attached to the particular orebodies being mined in the Grey Eagle claim. While this is a novel point, he says definitely, that the defendant would be entitled to judgment even if there had been no horizontal movement.

The Judge frankly ignored geologic history and based his decision on "conditions as the miners find them in the ground today". There was no conflict between the statements of the geologists who testified for both sides in so far as matters of physical fact were concerned. They did differ as to the interpretation of the term 'apex' within the meaning of the statute; but it is the province of the judge himself to construe the meaning of the law. The lack of geological issue is presumptive evidence that there necessarily must have been a 'practical' issue, or no basis for a suit would have existed. The Court puts its finger on this practical issue when it says, to quote from the record: "In other words, if this case should be decided upon the theory of origin, the plaintiff would not own the Tom Reed vein as found within the Bald Eagle and Grey Eagle claims, but that property might be successfully claimed by some owner of barren ground a few thousand feet away".

That this statement, particularly if the word "barren" be deleted, is entirely reasonable can be seen clearly by reference to the accompanying sketch, in which the full lines represent conditions as shown on the exhibits before the Court and the dotted lines represent one of a dozen imaginary but entirely plausible hypotheses. The line *AB* represents the surface in an earlier geologic period; *CD* is a continuation of the present surface; *EF* is a fault similar to the Mallery fault. *GH* is a lode outcropping at *G* in a claim owned by a third party. Geologists could readily prove the identity of the main vein in the Grey Eagle claim as being the 'downward' extension of the lode *GH*; incidentally a possible horizontal dislocation along the fault-plane *EF* conceivably might have thrown the ore deposits miles apart without preventing the establishment of a valid geologic connection. But aside from this, it is clear that both the Tom Reed and United Eastern companies should be held

to account for the appropriation of ore that did not belong to them—if the law were carried out in exact accord with the geologic theory of the structural relations of ore deposits. Perhaps Judge Bollinger actually visualized some such set of conditions; perhaps intuition told him of the complications that might arise; at any rate, we have his word for it that common sense and practical considerations decided the issue, whereas several thousand pages of expert testimony had served little purpose but to encumber the archives of the Mohave county courthouse.

The suggestion has been made that a practical arrangement might be effected whereby the judge would appoint one competent geologist of commanding professional standing to make an impartial report on the area involved in litigation. He would be authorized to have performed the mine-work necessary to establish important facts, and to engage technical assistance if necessary; his sole object would be to obtain and report such information as would clarify the issue for the benefit of the Court. He would prepare a few plain, accurate, and informative maps to replace two huge arrays of artistic but distorted affairs usually offered as exhibits. As an unbiased representative of the court, he would advise the judge regarding the essential features of geologic history, dealing with the genesis of the ore and the probable movement of the enclosing rocks before and after its deposition. It is contended that a man delegated to perform such a task would take exceptional professional

pride in his work and that he would come as near the truth as is humanly possible. It may be objected that too much would depend upon the knowledge, judgment, and integrity of one man; as an alternative a commission of three might be appointed to collaborate. Almost any one of the group of scientists who have participated in recent trials would be competent in every way either to serve alone or to co-operate with others as an unprejudiced advisor to the court. Of course, partisan testimony of the kind that Judge Bollinger characterizes as 'practical' would be admitted and the lawyers would not relinquish their cherished prerogative of presenting their oral arguments and their printed briefs.

Some such procedure would have obvious advantages. It certainly would be far more satisfactory, from every point of view, for the judge; likewise for the geologists, unless perchance some of them have become so accustomed to the stimulating mental diet afforded under the present system that geology unseasoned with the spice of contention would be unattractive. Some method like that proposed, obviously, would be more economical; the cost of preparing for, and trying, the case would be reduced many-fold. One all-important consideration remains; the purpose of court proceedings is to determine the issue as nearly as may be in accord with the facts and the law. If this purpose is best furthered and if the rights of the litigants are best protected by the present prevailing custom, the keystone of which is partisan 'expert' testimony, with all its inherent wastefulness, there is no more to be said.

It is probable that Judge Bollinger absorbed more light from the testimony of the geologists than he realizes; nevertheless their testimony was not vital to the outcome of the suit at Kingman; there is sound basis for the belief that Judge Bourquin sensed the solution of his knotty problems as being elsewhere than in the intricate meshes of geologic theory; and strong evidence points to the conclusion that purely practical considerations convinced Judge Johnson of the direction in which justice lay in the Bingham controversy. All of which may, or may not, be accepted as reason for concluding that the ends of justice may be served quite as well with a much more sensible procedure for bringing geologic evidence before the Court.

Has the litigation of apex disputes become a travesty on justice; is one of these suits a huge burlesque, or would it be one if it were not for the great sum of money involved and the large amount of conscientious study and serious effort that it represents; have the geologists who serve as expert witnesses, the most ridiculous parts in the performance, namely, that of 'heavy' comedians, to be alternately coaxed and pampered, derided and browbeaten by opposing counsel? If these things are so, are they caused in part at least by a juridical procedure that is radically wrong, more particularly with respect to the placing of self-respecting geologists in the equivocal position of acting at one time both as truth-seeking scientists and intensely enthusiastic partisan advocates? Is there need for reform based on common sense?

Company Reports

HEDLEY GOLD MINING COMPANY, LIMITED.

Report for the year ended December 31, 1920.

Property: Mine and mill in British Columbia.

Operating Official: G. P. Jones, general superintendent.

Financial: Loss on year's operations, \$1940.59.

Development: 690 ft., with 2210 ft. of diamond-drilling.

Production: 38,053 tons of ore was milled of an average assay value of \$8.72; recovery was \$234,985.55, or 87%.

General: The mill operated from March till September only; development work was carried on during the remainder of the year.

TONOPAH EXTENSION MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill in Nevada.

Operating Official: J. G. Kirchen, general manager.

Financial: Net income, \$261,615.79; available surplus, \$63,982.51; dividends, \$258,542.48; dividends to date, \$2,684,526.55.

Development: 9114 feet.

Production: 89,022 tons milled, of an average grade of \$15.591 per ton; tailing loss, \$1,232 per ton; receipts from sale of gold and silver, \$1,283,520.72.

Remarks: Sodium cyanide (100%) consumption per ounce of bullion was 0.1555 lb.; zinc consumption per ounce of bullion was 0.0597 pound.

CENTRAL EUREKA MINING COMPANY

Report for the fiscal year ended April 28, 1921.

Property: Mine and mill in California.

Operating Officials: A. S. Howe, superintendent; H. Warington, assistant superintendent; W. J. Bryant, mine foreman; G. P. Harper, mill foreman.

Financial: Bullion and concentrates account, \$424,068.08; balance in treasury, \$15,962.58; dividends, \$94,227.84.

Production: Tons mined, 37,856; milled, 37,986; extraction, \$11.004 per ton milled; tailing, \$0.898 per ton.

Development: 2073 feet.

KENNECOTT COPPER CORPORATION

Report for the year ended December 31, 1920.

Property: Mines and mills near Kennecott, Alaska.

Financial: Operating revenue, \$8,437,190.62; operating cost, \$5,185,700.01; total income for the year, \$6,477,020.82; balance to undivided profits, \$5,197,334.44; dividends, excluding capital distributions amounting to \$2,787,081, \$2,787,081.

Development: Kennecott, 13,630 ft., with 14,936 ft. of diamond-drilling; Latouche, 8652 ft., with 4846 ft. of diamond-drilling.

Production: 674,472 tons, containing 4.175% copper, mined; 91,991 tons to smelter, of average copper content of 28.50%; receipts at smelter, 51,365,261 lb. copper and 507,726.88 oz. silver.

DALY WEST MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines in Utah.

Operating Officials: O. N. Friendly, general superintendent; G. R. McKay, mine superintendent.

Financial: Receipts, \$622,274.22; expenditures, \$343,744.94; net gain, \$278,529.28; dividends, \$225,000; dividends to date, \$6,831,000.

Development: From Judge M. & S. Co. levels, 2810.5 ft.; from Daly West levels, 3530 ft.; by fissure systems, Daly vein, 1188.5 ft., middle vein, 220 ft., back vein, 2121.5 ft.

Production: Mine, 22,002 tons; shipped, 10,825 tons; metal contents of ore sold, 505,506 oz. silver, 240 oz. gold, 3,364,606 lb. lead, and 341,465 lb. copper, which sold for \$615,464.45.

JUDGE MINING & SMELTING COMPANY

Report for the year ended December 31, 1920.

Property: Mine, mill, and electrolytic zinc plant in Utah.

Operating Official: O. N. Friendly, general superintendent.

Financial: Receipts, \$1,133,309.87; expenditures, \$892,003.36; dividends, \$180,000; balance, \$61,306.51.

Development: 2793 feet.

Production: Mine, 41,316 tons; shipping, 9150 tons containing 483,890 oz. silver, 649 oz. gold, 7,877,121 lb. lead, and 359,186 lb. copper. The electrolytic plant produced 2,808,000 lb. of premium-grade zinc.

General: The zinc concentrate produced is being stored until such time as the metal market and the final decision of the Commission make a resumption of operations possible.

UNITED EASTERN MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill in Arizona.

Operating Officials: R. W. Moore, general superintendent; J. W. Carroll, mine foreman; B. C. Staiger, mining engineer; E. M. Bagley, mill superintendent.

Financial: Receipts, \$2,192,633.77; expenditures, \$1,800,015.19; dividends, \$981,360

Development: Assured reserves, 222,086 tons of an average value of \$18.46 per ton.

Production: 102,326 tons for a yield of 101,161.242 oz. gold, and 75,737.872 oz. silver.

General: The mill superintendent reports satisfactory operation of the mill, with a recovery, based on metals actually produced, of 97.05%. Skimmings recovered during 1920 were included; without this the recovery would have been 96.80%. Aero brand cyanide was experimented with; the results were encouraging; a saving of about 3 cents per ton milled was effected by substituting this for the sodium cyanide previously used. Steel slugs are being used in the re-grinding mills; these are made from discarded drill steel. A saving of about 4 cents per ton has been effected by this innovation.

PHELPS DODGE CORPORATION

Annual report for the year ended December 31, 1920.

Property: Mines, mills, and smelters in Arizona, New Mexico, and Sonora, Mexico.

Operating Officials: P. G. Beckett, general manager; Copper Queen branch, G. W. Dowell, manager; Morenci branch, J. P. Hodgson, manager; Burro Mountain branch, E. M. Sawyer, manager; Stag Canyon branch, W. D. Brennan, manager; Moctezuma Copper Co., H. T. Hamilton, manager; Bunker Hill Mines Co., J. H. Davis, superintendent; Phelps Dodge Mercantile Co., W. A. Meyer, general manager.

Financial: Income, \$35,930,177.72; expenses, \$35,197,066.21; net income, carried to balance sheet, \$733,111.51.

Dividends: Regular dividends to the amount of 10% were declared during the year.

Production: Ore extracted, 1,565,547 tons, including 89,038 from lessees, and 261,277 mined by steam-shovel; 233,914 tons went to the leaching plant at Bisbee, 734,446 tons was concentrated, and 597,187 tons was direct-smelting ore. Copper-bearing material smelted at the Copper Queen works was 787,985 tons. Copper bullion produced contained 17,269 oz. gold, and 1,643,115 oz. silver.

Development: 226,659 feet.

General: Freight-rates and taxes in the State of Arizona have reached a point where they are seriously menacing the output of any but high-grade ore. Western taxes alone having trebled since 1914.

REVIEW OF MINING

PROPOSED REVISION OF MINING LAW

H. Foster Bain, Director of the Bureau of Mines, has made public the report of the Committee on Revision of the Mining Law, appointed by the Director of the Bureau on January 23, 1917, following the recommendation of the Council of the Mining and Metallurgical Society of America. The members of the Committee are: W. R. Ingalls, Walter Douglas, J. Parke Channing, J. R. Finlay, John Hays Hammond, Hennen Jennings, and L. D. Ricketts. Horace V. Winchell was appointed to take the place of Mr. Jennings at the time of his death. The report was made after exhaustive discussion, and after taking a referendum vote upon a

carded actual discovery of a mineral deposit as a prerequisite to the location of a claim, but we provide that such discovery must be made before the claim may be patented and complete title to it be thereby secured. We allow a liberal, but not unreasonable, time between location and the necessity for applying for patent. We provide for the location of large areas. We require the lines of mineral claims to conform to the subdivisions of the general land survey, there being good reasons why they should and no good reasons why they should not. We modify the present requirements of assessment work for the holding of claims. All of these changes are made with the contemplation that

Chart Showing Fluctuations in the Price of Metals. Reproduced from 'Steel and Metal Digest'

questionnaire submitted to sundry professional and technical organizations throughout the country.

The opinion expressed by these questions was practically unanimous on three points, namely, that the extra-lateral features of the existing law should be abolished; that the requirement of discovery as a prerequisite to the location should be abolished; and that otherwise the provision of the existing law should be preserved both as to terms and as to language as far as possible.

The report of the committee is a careful, deliberately considered opinion to be used as a basis for the drafting of a bill to revise, amend, and codify the laws relating to the location of mining claims. In his report to the Director of the Bureau, W. R. Ingalls, chairman of the Committee on Revision, says:

"We have abolished the extra-lateral features of the existing law and have confined proprietary rights in the minerals to what are comprised within the vertical projections downward of the surface lines of a claim. We have dis-

the development of new mines in the future will be to a large extent in a different way from what has prevailed in the past.

"In pursuance of the same thought we have introduced an entirely new provision, namely, to afford means to operators of mines to acquire large areas of land for storage purposes. The conditions of modern mining lead to the transfer of material from its original place to another place to the amount of many millions of tons. Such material, especially when it be mill tailing, contains quantities of metal unextractable under present conditions, but possibly capable of extraction at later dates by virtue of improvements in the arts. In the past untold millions of dollars have been wasted by the dispersal of such material by pouring it into streams. This committee is unanimous in the opinion that in the interest of the conservation of natural resources no mine operator should be permitted to waste such material, but should be required to preserve it in the interest of future generations. It follows naturally from the idea of such preservation that

ground must be afforded for the purpose, and the committee proposes therefore to give to mine operators the right to acquire unlimited areas of the public land for such purposes. It guards against the abuse of such a right by the requirement that such land must be paid for at rates per acre very much higher than obtain with respect to any other public land, that such payments buy only the surface rights, that the acquisition of such areas under such terms confer nothing of the underlying mineral rights, and finally that each application shall be approved by the Secretary of the Interior.

"The bill that we have drafted covers the location of mineral deposits of all forms, whether in lodes, disseminations, or in alluvial placers, except that it does not cover the location of coal mines, petroleum lands, and the several forms of mineral deposits that now come under the leasing acts. Apart from the changes that have been indicated in this report, the accompanying bill follows very closely the lines of the existing mining laws, and preserves their language to the maximum extent possible. The existing laws which are now scattered through the statutes have been assembled and codified in one law. There is nothing in the accompanying bill that changes any rights to mineral deposits that have been acquired under existing or previous laws."

NEW POWER-PLANTS FOR UTAH MINES ARE PROJECTED

At a meeting of representatives of the principal coal mining companies in the State on June 1, tentative plans for the erection of a large steam-power plant in Carbon county were discussed. F. A. Sweet, of the Standard Coal Co., stated that the coal-mining companies believed such a plan feasible, and that it would reduce their present power bills fully 50%. Since October 22, 1920, the coal companies have been compelled to pay schedule rates for their power, as the Public Utilities Commission abrogated all 'special' contracts on that date. It is believed that a power-plant can be constructed at a cost of \$1,000,000 that will supply the principal coal producers with power. It is proposed to use slack coal, now being sold at a loss, in the generation of steam. It is also stated that the metal-mining companies in the Park City district have been giving attention to the question of a joint power-plant in that vicinity for the purpose of supplying power at a lesser rate than they are now compelled to pay to the Utah Power & Light Co. Attorneys for the Utah Copper Co. recently declared that that company could produce its own electric power in a steam-plant for 30% less than the existing rates as sanctioned by the Utilities Commission.

ARIZONA

Bisbee.—Twenty feet of high-grade sulphide ore has been cut in an intermediate drift between the 600 and 700-ft. levels of the Boras mine since January 1, when ore shipments from the Boras were discontinued. The shaft has been sunk 100 ft. and a drift has been run to a point under the orebody discovered on the 600-ft. level. A raise and drift have developed the ore. M. J. Elsing is manager for the company.—In the adjoining Nighthawk mine a cross-cut from the main drift on the 650-ft. level penetrated rich sulphide ore some weeks ago. The ore contains bornite and is rich in silver. James McKenna is superintendent.

Dos Cabezas.—Unusually fine ore has recently been opened by the Le Roy Consolidated Mines Co. The extent of the shoot has not yet been determined, as only a small amount of drifting has been done. A small force of men has been employed in development work for over a year. The ore is high-grade, containing gold, silver, and lead.

Hayden.—The Ray Consolidated Copper Co. milled 347,-

778 tons of ore, averaging 1.641% copper, during the first quarter of 1921, and the average extraction was 77.09%. The production of copper from concentrates was 8,802,186 lb. and from direct smelting are 144,339 lb., making a total production of 8,563,596 lb., as compared with 10,617,651 lb. for the preceding quarter. The average net cost of production was 15.65c. per pound of copper.

Kingman.—Renewed work on the 700-ft. level of the Aztec claim of the Tom Reed Gold Mines Co. has opened high-grade milling ore. This shoot was first opened two years ago, but the flow of water was so great as to cause discontinuance of the work.

The Arizona Rand Gold Mine Co. has let a contract for 250 ft. of work on the 100-ft. level of the Roadside mine to R. W. Shaw. Unwatering and timbering are now being done in preparation for drifting, which will be commenced within a week. The Roadside mine is situated in the Union Pass district.

The shaft of the Katherine Extension has now entered lode-matter for a depth of 20 ft. Overburden proved to be only 100 ft. thick. The shaft is to be continued to the 200-ft. level, from which point lateral exploration will be done.

The ore in the east drift on the 700-ft. level of the Gold Ore shows a width of 5 ft. and assays as high as \$20 per ton. The drift has now been carried 125 ft. in the vein, which has continued to widen. Negotiations are under way to raise sufficient money to sink to the 800-ft. level. It is stated that the present orebody is as large as any opened to date in the Gold Ore mine.

Drifting on the 100-ft. level of the Dardanelles mine has opened 30 in. of ore which assays \$37 to \$40 per ton. This high-grade streak is in a 12-ft. vein. A raise from this level to the level above is now being run in good ore. Two cars of ore are now ready for shipment to the smelter.

The Katherine Mohawk Mining Co. has secured a permit to sell 200,000 shares of treasury stock. The property of this company approaches within 600 ft. of the Katherine mine, in which large bodies of high-grade gold ore have been recently opened; it is located on an outlying vein.

Morenci.—The Arizona Copper Co. ceased operations on May 31. The Arizona is the last copper company in the Clifton-Morenci district to suspend operations, the Phelps Dodge having closed a month ago. The Stargo silver mine is operating a small force and contemplates the erection of a mill.

Tombstone.—Charles P. Blanton has acquired a group of claims known as the Gold Camp, situated 16 miles north of here. He will develop the property at once. Other claims are being prospected in the vicinity.

Notices of sheriff's sale have been posted for the sale of nine claims of the Dragoon Copper Mining Co. The sale is to satisfy a judgment secured by W. J. Smith for \$850.

Messrs. Hammond and Sibring of the New Mining & Milling Co., who are to operate the mines and dumps of the State of Maine mine, have arrived at Tombstone and are to commence construction immediately. These gentlemen and associated Tucson interests are behind the undertaking.

CALIFORNIA

Carrville.—The Coffee Creek Gold Mining Co. has been incorporated by C. J. Kerr, W. A. Crank, and Lawrence J. Kennedy. An option has been taken on the Golden Jubilee mine on Coffee creek.

Forest.—Construction work on the new 10-stamp mill at the Kate Hardy mine is progressing steadily. Orders have been placed for the 1250-lb. stamps and other machinery for the mill and for the entire amount of lumber needed in the construction of the plant. It is hoped to have the mill running early in July. All the bins of the mine are filled with broken ore ready to be crushed, so very little underground

work can be done until the mill is put in condition to handle the ore.

Grass Valley.—The managers of the three leading mines published a letter on June 2, addressed to the Mine Workers' Protective League, stating that the mining problem here had resolved itself into a question of lower operating costs or closing the mines.

It is announced that a lower wage scale will be effective July 1. No specific cuts are mentioned, but it is pointed out that the mines on the Mother Lode have adopted a wage-scale based on \$4 per day for miners and \$3.50 for shovelers. This is about \$1 per day under the scale now in effect. The statement, which is signed by George W. Starr for the Empire Mines, A. D. Foote for the North Star Mines, and John A. Fulton for the Idaho-Maryland Mining Co., gives a long review of mining conditions here and intimates that heavy losses have been sustained in an effort to keep the mines open and the men employed. For a time it was hoped that the McFadden Bill would bring relief, it is stated, but the producers are now convinced that Congress does not intend to come to their rescue. The necessity of working both low-grade and high-grade ore as it is encountered, instead of 'robbing the mine' by taking out only the high-grade ore is pointed out. The statement closes by saying: "It is the expectation of the management that the employees will recognize the fact that a reduction in the scale of wages will be made reluctantly and only after the failure of every other means of relief from the condition which now jeopardizes the gold-mining industry". All of the mines of this vicinity will be affected by any change in scale, and approximately 1000 men are involved.

The Mine Workers' League made a statement that is replete with sarcastic references and pokes fun at the version of the mine-owners concerning the need of extracting both high-grade and low-grade ore.

The outcome of the exchange is expected to be the appointment of committees to confer concerning a wage-scale to take the place of the one now in force and which will expire on July 1.

The Empire Mines Co. for the present has suspended operations at the Pennsylvania mine. F. W. Nobs, superintendent, states that the ore available is too low-grade to be profitably mined under present conditions. Large deposits exist which may be mined at a later date.

Magalia.—B. Wisebaum, who controls the old Steifer gravel mine, has unwatered the 500-ft. shaft and has 30 men employed. After obtaining millions from the mine, the Steifer brothers lost the 'lead' and for years endeavors to again find the goldbearing strata were unsuccessful.

Melones.—During April, the Carson Hill Gold Mining Co. crushed 15,000 tons of ore at a total mining and milling cost of \$3.74, as compared with \$4.10 during February. It is expected that the cost for May will not be more than \$3.50 per ton. Work on the 2000-ft. level is progressing satisfactorily, and the workings should soon reach a point under the orebody developed on the 1700 and 1750-ft. levels; a raise will be started to develop the ore.

Portola.—Three gold bars, valued at \$6720, were sent to the United States Mint at San Francisco, and forty cars of concentrate, with a total value of \$5000, were shipped to the smelters in Salt Lake valley from the Gruss mine. This represents the output for 28 days during May; the bullion is from the first clean-up since the installation of the new electric equipment. During the month, 1400 tons was mined and milled at a combined cost of \$2.25 per ton, according to J. W. Gruss, manager. He states that during the last three months, development work has disclosed two new glory-holes containing \$8 ore.

Quincy.—The 10-stamp mill of the Schaffer Consolidated Gold Mining Co., at Seneca, has been fully repaired and is

again in operation. This property is considered to be one of the best gold-quartz mines in Plumas county, and a large amount of gold has been taken from it. Development work has been carried on all winter and high-grade ore is blocked-out. Eastern capital is behind the corporation. J. J. Reilly is in charge of operations.

The Reinmiller Copper Mining Co. has resumed work at its property, adjoining the Engels mine, after an idle period of several weeks. Diamond-drilling has given satisfactory results. The last hole drilled showed low-grade ore within 50 ft. of the beginning of the hole. A nine-foot core gave an assay of 3.166% copper. John Reinmiller is personally directing the work, after an illness of several months.

Representatives of the Mason Valley Smelter Co. are at their property near Genessee, which they have under bond and lease from Rufus Barnes and J. E. Murphy. Last fall a road was built to this property from the main highway, a camp was built, and everything placed in readiness for development work this spring. This property lies within five

The Old Eureka Mine at Sutter Creek

miles of the Walker mine, on the southern end of the copper belt.

Development work is also being done at the Ruby copper mine, and the Feather River Copper Co.'s property, adjoining the Engels mine on the south. Messrs. Long and McIver of Arizona are interested in these two properties. J. E. Bush is manager of the Feather River mine, and Lester Williams is in charge of the Ruby property.

Redding.—The offices, store, and staff headquarters of the Mountain Copper Co. have been moved from the Iron Mountain mine to the Hornet mine, two miles distant. Only one train daily is run over the Iron Mountain railroad, now that the output of the Hornet has been curtailed to 300 tons per day.

Sonora.—Sale of the famous Excelsior gold mine for \$19,000 to J. W. Crossman and associates, of San Francisco, has been announced by the former owners, Sarah A. Hall and Fred Sutton, of Sonora. The new management has arranged to prospect for the rich shoot that faulted several years ago.

Sutter Creek.—The suspension of operations at the Old Eureka mine, recently announced, comes after an expenditure of more than \$1,000,000 in the purchase of property, the equipment of the mine with modern machinery, and the sinking of a 1000-ft. shaft. Extensive development work, however, failed to uncover the expected ore. The mine is credited with a yield of more than \$20,000,000. The property was formerly owned by Hetty Green of New York.

COLORADO

Alma.—Mining activity in the Alma-Sacramento district is steadily increasing with more properties active than be-

fore the War. Operations were resumed at the Brownlow a few weeks ago and a lode 24 ft. between walls has been opened by cross-cut tunnel. Indications for finding ore are good.

A hydraulic-placer plant has been installed in Buckskin gulch; washing started on June 1.—Operations have been resumed in the Mascotte tunnel, planned to penetrate the Mosquito range for drainage, transportation, and mining purposes. Several veins have already been cross-cut and will later be developed.—The Dolly Varden and Moose mines are being prepared for resumption.—The Hill Top will resume shipments when metal prices improve. A small shipment recently sent out from the Champaign returned better than \$1000 per ton in silver and gold.

Breckenridge.—Many properties closed down during the winter have resumed or are preparing to resume operations. Among these the Tymos Mines Co. is installing a pumping plant at the Deep shaft on Shock hill. The Warrior Mark company is unwatering the old Kaiser shaft, where a vein of silver-lead ore was uncovered when the shaft was last worked in the '80s. Lessees on the Missouri who were driven out by seepage from the melting snows are also preparing to resume. This lease has around 100 tons of lead carbonate ore on the dump awaiting a higher market. The King Solomon Mining & Development Co. is making preparations to resume on its property below Breckenridge at Frisco; the tunnel is to be extended. The June Bug lessees will make a shipment of high-grade silver ore from this Prospect gulch property later in the month, estimated at better than 300 oz. per ton. One of the Standard mine lessees will make a 50-ton shipment to the A. V. smelter at Leadville, estimated at around 100 oz., as soon as the road is in condition for hauling.

Cripple Creek.—George Bernard and associate lessees, who recently secured a long-time lease on the Elkton, has opened a new orebody in Raven territory north-west from the main shaft by a cross-cut at the 100-ft. level. This territory was productive above 600 ft., and the Elkton company was unable to prospect the ground on its own account through adverse financial conditions. Royalties paid on ore shipped are expected to place the finances of the company in sound condition.—Sub-lessees from the Victory Gold Mining Co. are mining ore averaging \$24 per ton and shipping from 4 to 6 cars per month from the Howard shaft of the Mary McKinney Mining Co.—Shipping of milling-grade ore from the Rittenhouse mine will be started by lessees now opening a promising shoot at the 400-ft. level.—The Ingham on Raven hill, owned by the Doctor-Jack Pot Mining Co. is again producing under lease.—Ore-reserves at the Cresson are steadily increasing and production continues heavy. The treasury reserve is building up but no dividend is anticipated until tax-rulings are adjusted.

Silverton.—The San Juan Golden Fleece Mining Co. has acquired additional lode claims on Treasure mountain adjacent to the Golden Fleece and is making arrangements for their development. Adits already started have exposed known producing veins in nearby properties and samples taken have assayed from \$20 to \$62 silver with fair gold content.

IDAHO

Coeur d'Alene.—According to reports received at Spokane, Portland parties have taken an option on one-half of the capital stock, consisting of 1,000,000 shares valued at \$150,000, of the Sonora groups at Burke, situated near the Hecla and Hercules mines.—Lessees working on the No. 3 tunnel of the Western Union mine are re-timbering a raise and as soon as work is finished will resume shipments. Another car of high-grade ore was recently shipped by the lessees working on No. 4 tunnel. They are running a cross-cut to the north vein, where still better ore is expected, as

ore in this vein found on the No. 3 level by the old H. E. M. company was the best it had.—Seams of ore in a strong vein are reported in the face of the west drift in the Cedar Creek property. Work was resumed a few weeks ago.

Development has been resumed by the Rex Consolidated Mining Co. The Okanogan vein, parallel to the Rex, is the objective of the present work. It will be reached by a cross-cut from the Rex workings. Two shifts are working.

Directors of the Hecla Mining Co. have declared a dividend of 8c. per share and voted to join with officials of the Bunker Hill & Sullivan company in the purchase and development of the property of the Star Mining Co. Eight cents per share amounts to \$80,000, the first dividend the company has paid this year. The Star is considered one of the great undeveloped mines of the Coeur d'Alene. It adjoins the Morning mine owned by the Federal Mining & Smelting Co. Between the Star and Federal companies a suit was tried to determine the ownership of ore which the Star claimed the Morning mine had taken out of Star ground. The Star won and the Morning must pay a large sum for the ore extracted. The value of this ore is yet to be determined, but it is estimated at between \$500,000 and \$1,000,000. The Bunker Hill & Sullivan and the Hecla have been working in close harmony for several years, the former company smelting the ores of the Hecla. The Star deal brings the two companies closer together.

MICHIGAN

Houghton.—Quincy is maintaining its four-day-per-week schedule and is down to the lowest possible minimum of production, getting out not much more than a quarter of the normal amount of rock. A good mass-copper yield has aided materially in reducing costs and with mill improvements and economies effected the cost per pound is now down to 14½c. as compared with 19.16c., including construction, for the year 1920. With a reduction this year in the price of coal and other materials, cost could be reduced to nearer normal, owing to the fact that wages are back to practically a pre-war basis. Quincy costs in 1916 were 12.58c. per pound, and 9.64c. in 1915. In the Quincy stamp-mills, where the installation of re-grinding equipment resulted in a saving of 2,345,000 lb. of copper last year, all but one unit have been supplied with re-grinding sections. When that unit is so equipped a still larger recovery will be possible. Coupled with this saving is the increase in yield, which was 3.47 lb. greater in 1920 than in 1919. The tenor of the 'rock' in the present openings and stopes gives assurance that this yield can be maintained.

The district appears to be weathering the depression caused by the shutting down of the Calumet & Hecla and its subsidiaries without any noticeable distress. A composite report of the banks of the 'Copper Country' shows only a negligible falling off in deposits, the total now being \$19,169,254. It is due to the fact that the miners as a class have been thrifty and have some money saved up that they have managed to get along to date. There have been no failures among the business houses and the situation generally is better at this time than had been expected. Approximately \$600,000 will be spent on road work this year and this will provide jobs for men most in need of them. The Calumet & Hecla is supplying its employees with land for garden plots and plowing the ground. Practically every family will raise enough vegetables for summer and winter use.

MONTANA

Butte.—It is reported that 6 ft. of high-grade copper ore has been opened on the 2300-ft. level of the Colorado mine belonging to the Davis-Daly company. Excellent ore is also coming from the Hesperus vein, being mined by lessees through the Butte-New England shaft just south of the Colorado.—An increased output of silver ore is reported

in the Butte district. In the Elm Orlu mine 20-oz. silver ore has been opened on the 800-ft. level. Effort is being made to find several rich ore-shoots on the 300-ft. level.

Cross-cutting on the 1600-ft. level in the Main Range mine of the Tuolumne Copper Mining Co. is progressing rapidly. The objective is the Spread Delight vein, which should be reached with another 150 ft. of driving.

Libby.—The Lukens-Hazel company is erecting a commodious boarding-house near its mill. Development work is being pushed rapidly. An underground station and hoisting plant for the sinking of a shaft were completed recently and actual work has been started. A depth of 250 ft. is planned.

St. Regis.—Gold ore assaying \$500 per ton is reported to have been found on the Democrat group of claims situated 5 miles south of here.

NEVADA

Eureka.—The 400-ft. Catlin shaft of the Eureka Croesus is to be sunk to 800 ft. This shaft, the main shaft for development and the extraction of ore, is equipped with machinery ample for sinking to this depth.

Goldfield.—The Florence company has suspended operations for an unannounced reason. The lessees continue work as usual. The stopping of work comes as a surprise, following as it does the optimistic statements of L. E. Whicher, president of the company, on a recent visit to Goldfield. Driving of a cross-cut west from the south-east cross-cut on the 358-ft. level was well under way when work was stopped and other prospecting on this level had been started. The Grandma has cross-cut 55 ft. east from the shaft on the 1000-ft. level toward the extension of an ore-shoot found in a winze from the 815-ft. level. The cross-cut is now in mixed shale and alaskite. The Great Bend, 214 ft. from the main raise from the 375-ft. level, has stopped work on the intermediate level. The intermediate level was being driven in the vein and as it was continued east the ground became so bad that work had to be stopped. Good assays were obtained all along this drift, but an orebody was not found. Work has now been started on the 375-ft. level, where a cross-cut is being driven north into the foot-wall of the vein. A drift will be driven east in this wall, with cross-cuts west into the vein at 50-ft. intervals.

Kennedy.—A shipment of five tons of silver ore from the Independence mine in the Kennedy district, 60 miles south of Winnemucca, had a gross value of \$185 per ton. The ore is quartz containing silver in both chloride and sulphide form. The vein, 3 to 4 ft. wide, is at a contact of lime and porphyry. No work has been done below a depth of 15 feet.

Locke.—Glenn D. Cook has found a body of high-grade silver ore 75 ft. from the surface of the Jersey claim belonging to the Pershing County Mines Co. The discovery seems to verify the diagnosis by Mr. Cook of the geology of the mining property and to warrant the sinking of a deeper shaft, which will be commenced at once.

Round Mountain.—The flow of water into the reservoirs of the Round Mountain company has increased rapidly in the last two weeks and four giants are in use. Continued cold weather and snow through May make certain the longest season in the history of the company and assure a big return. About 75,000 cu. yd. has been treated to date and up to the middle of May the head-boxes had yielded \$41,000.

Silverhorn.—George Z. Smith has found remarkably high-grade ore on his No. 2 lease on the Nevada Silver Horn property. Specimens assay more than \$2000 per ton and a lens 10 ft. wide averages \$100 per ton. This rich ore is being sacked and shipped. Smith also has a lease on the Silver Dale. He has opened up an orebody but as yet has not found a high-grade streak.

Tonopah.—It is reported that 50 men are employed by the

Belmont, 50 by the Tonopah Extension, and that the Tonopah Mining has men enough to work on a good scale. In a statement issued to stockholders by the Belmont, announcing the passing of a dividend, Clyde A. Heller, president of the company, says: "The new wage-scale is absolutely necessary if the thousands of tons of low-grade ores available at your property at Tonopah are to be treated, thereby prolonging the life of the mine. Even with the reduction the new scale is higher than that of any other mining district in the country. There are many unemployed men in other districts and your property will be operated under the new scale as soon as labor can be brought in." More men are being brought into Tonopah now by the companies than at any time since the strike was declared. The strikers on the other hand are still confident they will win.

Tule Canyon.—The Silver Hills mill is now operating 24 hours daily and is making a recovery of 95%, according to reports, with the newly built cyanide plant working satisfactorily. A large amount of development work is being

Northern Nevada

done in various groups of claims owned or held under option by the Silver Hills.

Tybo.—A judgment for \$18,951 against the Louisiana Consolidated Mining Co. has been given in the district court at Reno in favor of an automobile agency that sold trucks to the company. S. R. Moore, of Tonopah, recently was appointed receiver for the company, which is reported to have liabilities of \$500,000, incurred in the attempts made in the last few years to put it on a paying basis.

Virginia City.—The new wage-scale, marking a reduction of 50 to 75c. per day, has been placed in effect on the Comstock Lode. All mines at Gold Hill and Virginia City are affected by the cut, which has been received without protest by most of the men. About 100 workers who refused to accept the reduction, all single men, have left for Reno and other points. Practically every mine in the district is working close to normal, with new men taking the places of those who walked out. Reductions in price of board and cost of commodities have been ordered by the United Comstock Mines Co., operating at Gold Hill. Establishment of the new scale means a considerable reduction of operating cost, and its acceptance proves the good feeling prevalent between employers and employees.

West Divide.—The West Divide is cross-cutting west from the bottom of a 63-ft. winze from the tunnel level to find the vein, which faulted at the 45-ft. point in the winze. A

cross-cut driven east from the winze failed to enter the vein, but it is the opinion that it will be found to the west. There was ore in the winze to the 45-ft. point.

Winnemucca.—A rich silver discovery is reported from the Mount Tobin district, 60 miles south of Winnemucca, between Pleasant and Jersey valleys. Two veins, one 60 ft., the other 16 ft. wide, have been uncovered at surface and traced for 300 feet.

UTAH

Park City.—Owing to the controversy between the A. S. & R. Co. and the Silver King Coalition Mines Co., no shipments of ore were made by the latter company during the week ended May 28. For the same reason, no shipments were made by the Daly-West Mining Co. The result was that shipments from this camp for the week ending May 28 totaled but 993 tons, of which the Ontario shipped 438 and the Judge allied companies 555. On June 1, the Silver King Coalition resumed shipments to the Murray smelter, although the differences between it and the A. S. & R. Co. were reported as not having been "entirely adjusted".

American Fork.—W. A. Richmond, mining engineer for the American Leasing Co., which is operating the Bellorphan property in American Fork canyon, reports that the company has opened a promising orebody, running, in picked samples, up to more than \$400 per ton and averaging around \$40 per ton. This ore comes from a vein about 1200 ft. from the portal of the adit, and at present has a width of above five feet, carrying silver, lead, and copper.

Beaver County.—Operations have been resumed by the Galena Mining Co., whose property adjoins the Beaver Copper mine, according to M. C. Morris, president. Contractors are at work driving a tunnel to catch the ore that was developed in the Galena shaft at a depth of about 240 ft. The tunnel is now in 260 ft. and should find the ore within the next 150 feet.

Big Cottonwood Canyon.—Hauling of ore from the bins of the Cardiff Mining company to Salt Lake Valley smelters was started on June 1. All ore mined by the company since last fall has been stored, 2000 tons is awaiting shipment. Conditions at the mine are reported as excellent. Last summer the company mined from 50 to 60 tons per day, averaging around \$50 to \$60 per ton.

Bingham.—Eighteen students of the State School of Mines, under the direction of Prof. Howard L. Baldwin, are taking a four weeks course in 'practical' mining in various mines in this camp. The students will spend some of their time in surveying claims on the surface, but the main object is to become familiar with practical underground operations.

The Utah Copper Co. is doing churn-drill work for the purpose of developing more fully the ore deposit near its northerly boundary. This work could not be undertaken before, owing to interference of steam-shovel operations. The company also has one steam-shovel at work, making a new entrance into the 'big pit' from the auxiliary yard. This work is being done by the company forces that were retained on the payroll when active mining ceased on April 2.

Exceptions of the Utah-Apex Mining Co. to the accounting filed by the Utah Consolidated Mining Co. were submitted to the United States District Court on May 31. The statement filed by the Utah Consolidated showed the value of the ore extracted, plus interest, to be \$658,000, whereas the Utah-Apex claims the amount to be \$1,421,467.88.

Ophir.—There is more activity here than for a number of years past. Recently a find of four feet of high-grade ore was made at the Ophir Silver Mines Co.'s property. This strike is in the upper tunnel on Claim No. 13, in what is known as the 'second Buckhorn' fissure, which is easily traceable from the Ophir Hill Consolidated property across

the canyon. The fissure is widening with depth, and sinking on the ore has begun. One sample gave returns of 152.5 oz. silver and 5.17% copper, although the average for the entire face is about 50 oz. silver. George H. Short, of Salt Lake City, is geologist and consulting engineer for the company.—George St. Clair has taken a lease on the Buffalo Consolidated property. A good showing of silver-lead ore has been opened at a distance of about 1000 ft. from the portal of the adit. A shipment of 100 tons, averaging \$5 in gold, 40 oz. in silver, and 40% lead, is piled upon the dump, awaiting transportation to the smelter.—In the Fink property high-grade silver-lead ore was recently opened. The Ophir Hill Consolidated mine and mill, owned by ex-Senator W. A. Clark, is now being operated on a one-shift per day basis. The company has a large tonnage of concentrate stored, awaiting better lead prices.

WASHINGTON

Colville.—The Chloride Queen mine, 14 miles north-east of here, is attracting attention. Five claims are included in the holdings of the company. A vein 25 to 30 ft. wide goes through the property. It contains streaks of rich galena-bearing material from a few inches to five to six feet wide. At one place a carload of ore was taken out and shipped, returning \$62 per ton. On the dump is approximately 5000 tons of ore estimated to assay \$22 per ton. Paul LePlant, superintendent, is directing development.

Oroville.—Smelter returns averaging 14 ounces more in silver than mine assays on a carload of ore shipped from the Pyrargyrite mine has encouraged a renewal of mining activity in this district, according to reports.

Stevens County.—Articles of incorporation have been filed for the Admiral Consolidated Mining Co., which has consolidated the Admiral and Denver properties. Arthur L. Hooper of Spokane is president. Work has been commenced on a new tunnel on the north end of the property. The hill is very steep and a 50-ft. tunnel is expected to give 150 ft. of depth. The ore is copper and silver. Two carloads shipped returned 6% copper and 7 oz. silver. Mr. Hooper is secretary-treasurer of the General Copper Mining Co., which owns property a mile north of the Admiral. Recently four feet of ore was uncovered on the surface, select samples from which run 6% copper and 5 oz. silver. The company will sink a 100-ft. shaft to explore this ground.

BRITISH COLUMBIA

Greenwood.—Work has been resumed at the Providence mine, after a shut-down of six months. The new compressor is in operation, and 25 men are employed underground.

Prince Rupert.—Pat Daly, the picturesque prospector of the Kootenays, who 'blew into' the Pennsylvania hotel, in New York, recently, minus many of the usual appurtenances that are supposed to constitute respectability, reports by wire that he has succeeded in bonding the Big Missouri, in the Salmon River district, and the Fraser, in the Marmot River district, and that substantial deposits have been put up. The Big Missouri is owned by Dan and Andy Linderborg, of Hyder, and during the whole of last season was bonded by Dan Mann and associates, who did a considerable amount of diamond-drilling and other exploratory work before relinquishing the option.

Revelstoke.—The Walters Investment Co., of Spokane, has purchased the Waverly-Tangier group, at the head of Downie creek, 28 miles north of Albert Canyon, on the C. P. R. main line, and a substantial payment has been made to bind the deal.

Vancouver.—Many Government geologists have arrived from Ottawa to undertake field work in various parts of the Province. Among the assignments for the coming summer

are the following: Victor Dolmage will make a survey of the Mainland channel from Burke channel to the north of Royal Island. W. E. Cockfield will again make his headquarters at Mayo; this is his eighth season in the Yukon. F. H. McLaren will investigate the oil-shales that have been attracting some attention on Graham Island, one of the Queen Charlotte group. S. J. Schofield will cover the Windermere district. W. L. Uglow has been assigned to a section of the North Thompson river. M. F. Bancroft will continue his investigations in the Lardeau district, while William Johnston goes to the Cariboo district. J. D. McKenzie, who is in charge of the local branch office, will study the coal deposits at Comox and the gulf islands. G. Hansen will cover the Kitsault river and other parts of the Alice Arm district. The Granby Consolidated Mining, Smelting & Power Co. held its annual general meeting recently; the annual report was not ready in time for the meeting but it was announced that the operations for the year would show a deficit, as the actual production of copper has cost slightly more than 12c. per pound, to which cost of transportation and marketing has to be added. During the last half of the year the cost of production was reduced 0.4c. The ore-reserve on December 31 was 10,986,420 tons, showing a depletion of 200,000 tons, which it is explained was caused by the effort to push production at the neglect of development in the early part of the year, when the price of copper was satisfactory, but had every indication of a fall. During the year 27,000,000 lb. of blister was produced and 25,000,000 lb. refined. The stock on hand at the end of the year was 20,000,000 lb., 3,000,000 of which was in process. The sales totaled 19,464,000 lb. Labor conditions were reported to be good, and rapidly approaching pre-war efficiency.

MEXICO

Arizpe.—Last month ore from the Chispas vein on the 900-ft. level of the Pedrazzini mine was found for the first time. Development to date has proved it to be of bonanza grade. It is expected to be more productive than the 842 bonanza pocket of the 800-ft. level. Drifting on the 900-ft. level, the present mine bottom, was started during last December; the first 160 ft. was driven upon a barren quartz vein jumping suddenly into first-class ore. The vein now averages nine feet in width and the ore produced, after sorting the waste by hand, averages over 300 oz. per ton in silver. Fernando Montijo is engineer for the company.

Chihuahua.—Large bodies of rich silver ore are being opened in the mountains east of Villa Ahuamada, the first Mexican town south of El Paso on the old Mexican Central railroad. The ores from this district are said to be similar in character and quantity to those in the old Santa Eulalia district that made Chihuahua famous as a mining centre. Recently large bodies of lead carbonate ore with high silver content have been shipped.

Durango.—The Sauces Mining & Milling Co. is erecting a new 100-ton concentrating mill at its Conde mine. This company is developing and making some shipments of dry silicious ore to the Chihuahua smelter. The ore will be treated on the ground as soon as the mill is complete. The long overland haul to the railroad station coupled with the high freight-rate greatly reduces the profit.

The Melchor Ocampo Mining Co., of which Attorney Jose Zurita is president, is completing a concentrating plant and has installed Stein flotation machines. This mill will shortly be in operation. The mines and mill are situated at Tejamén, about two days journey by pack animal over a rough trail from the Tejamén station. The machinery and equipment for the new mill were hauled over the trail in small parts requiring much time and expense.

San Juan de Guadalupe.—Albert Bange who has been operating his silver-lead mines in the Ramirez mountains

without interruption during the past fifteen years continues to ship to the Aguascalientes smelter which is operating two copper furnaces and preparing to blow in one lead furnace. — Capillas Rueda is working his mines in this district and shipping some high-grade silver-lead ore to Chihuahua. He expects to change these shipments to the Aguascalientes smelter as soon as the lead furnace is started.

Zacatecas.—August Reimers has filed on the Santa Barbara group of mines located in the municipality of Guadalupe. The property contains a vein of high-grade silver ore; a shaft is to be sunk. — Walter Palmer is working a large force of miners at his Parroquia mine. He is shipping about 150 tons of copper-silver-lead ore to the Aguascalientes smelter per week. At the present time this is the only mine of importance which is working near the city of Zacatecas. The Bote Mining Co. is doing some development work and repairing its cyanide plant but is not shipping at the present time.

ONTARIO

Beaver House Lake.—J. H. Rainville, president of the Argonaut, who has returned from a visit to the mine, reports that work at the 355-ft. level is meeting with excellent results, one vein having been cross-cut showing ore averaging \$27 per ton.

Cobalt.—The Mining Corporation of Canada has resumed operations at full capacity on its Cobalt properties, giving employment to about 240 men. Before closing down in January last the management had succeeded in reducing operating costs to 60c. per ounce, and having enlarged its mill capacity by about 50% the Corporation expects to be able to effect further economies and produce silver at a profit at present prices.

Options held by the National Mining Co. on the section of the Silver Cliff property below the 500-ft. level, and by the Northern Customs on the upper part of the mine, have lapsed and a plan of exploitation and development by Silver Cliff interests is in contemplation.

Kirkland Lake.—At the Ontario-Kirkland about 3500 ft. of drifting has been done on the 300 and 450-ft. levels, and about three years supply of ore is indicated. A three-compartment shaft, to be used as the main working shaft, is being raised from the 300-ft. level and about 100 ft. is completed. The construction of the mill is expected to be completed by September 1.

Buildings are being erected on the property of the Kirk Gold Mines, adjoining the King-Kirkland in the central part of Lebel township preparatory to surface exploration. The Kirk Gold is in the line of the strike of a promising vein on the King-Kirkland.

It is reported that a recent find at the 900-ft. level of the Kirkland Lake mine is regarded as important. Frank L. Culver, president, states that a diamond-drill driven horizontally passed through between 11 and 12 ft. of ore, 2 ft. of which assayed upward of \$60 per ton and 7 ft. contained an average gold content of \$20 per ton.

Matatchewan.—Asbestos mining is in progress in Bannockburn township in the Matatchewan gold area. Fifteen men are at work in charge of William Judge. For a preliminary test 30 tons is to be taken out and shipped. The district is handicapped by isolation from railroads.

Porcupine.—The Hollinger Consolidated is making a preliminary survey of the Kettle Falls water-power on the Abitibi river, 60 miles to the north, with a view to securing a supply of power. — Work has been started on the Big Dike, about four miles south of the Dome, by a small force under the direction of F. G. Heycke.

West Shining Tree.—The Wasapika Consolidated has ordered machinery for a 100-ton mill, which it is hoped to have ready for operation before the end of the year.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Frank L. Sizer has returned from Colorado.

J. M. Callow, of Salt Lake City, is in New York.

W. J. Loring was at Kingman, Arizona, recently.

Mark L. Requa is at the Adler Sanatorium, having undergone an operation.

Spencer Bishop has moved from Clifton, Arizona, to Berkeley, California.

Harry H. Stewart, of Deadwood, is now assayer of the Deadwood assay-office.

Richard M. Geppert sailed from New York on the 'Adriatic' on June 1 for London.

C. W. Whitley, vice-president of the American Smelting & Refining Co., is at Salt Lake City.

Claude Ferguson has moved from Swansea, Arizona, to Ono, in Shasta county, California.

Girard B. Rosenblatt has returned from a trip through Utah, Montana, Idaho, and Washington.

Hjalmar E. Skongor has returned to New York from Europe after an absence of three months.

Louis S. Cates, general manager for the Ray Consolidated Copper Co., is spending a few weeks at Boston.

Herbert R. Hanley has returned to Bakersfield, California, from an examination of the Silver Horn region near Pioche, Nevada.

J. C. Johnson, who has been at Miles City, Montana, now has an office as mining engineer and geologist at 600 Leary building, Seattle.

Newton A. Dunyon, superintendent for the Ontario Silver Mining Co. at Park City, Utah, has returned from a trip to Pioche and Silverhorn, Nevada.

J. R. Hockey, superintendent of iron mines for the Broken Hill Proprietary Co., arrived at Vancouver from Australia on May 28, on his way around the world.

Isaac H. Smith, of Peekskill, New York, has been appointed superintendent of the New York assay-office, succeeding **Verne M. Bovie**, who has resigned.

C. R. Forbes, Professor of Mining at the Rolla School of Mines, accompanied by a party of students, has been visiting mining districts in Arizona, New Mexico, Colorado, and Utah.

H. C. George, formerly chief engineer for the Wisconsin Zinc Co., has accepted the position of oil-recovery engineer with the U. S. Bureau of Mines, with headquarters at San Francisco.

H. H. Stout has resigned from his position as superintendent of the Copper Queen smelter to become consulting metallurgist for the Phelps Dodge Corporation, with headquarters at 99 John street, New York.

W. R. Appleby, Dean of the Minnesota State School of Mines at Minneapolis, accompanied by **W. R. Emmons**, Professor of Geology at the same institution, sailed from Seattle on June 3 for China on professional work.

Murray Innés, who for several years has been general manager of the New Idria quicksilver mine, was seriously injured on June 6 as a result of an accident that took place at California and Montgomery streets, San Francisco.

Howard R. Ward has removed his office to the Manufacturers Exhibition building, 45 West 18th street, New York, where he will continue his engineering practice, specializing in mine examination, and in the development and operation of non-ferrous metal mines.

Henry F. May, for the past three years special assistant to the attorney general in charge of litigation over the withdrawn oil lands, has opened an office for the general practice

of the law, in association with **Charles S. Wheeler** and **Charles S. Wheeler, Jr.**, at 609 Nevada Bank building, San Francisco.

C. A. Fisher, of the firm of Fisher & Lowrie, consulting geologists and engineers, of Denver, Colorado, has recently been appointed a delegate by the American Petroleum Institute to the first annual meeting of the International Chamber of Commerce to be held in London from June 27 to July 2. He sails from New York on June 14.

Obituary

Karl G. Roebing, president of the John A. Roebing's Sons Co., died at Trenton, New Jersey, on May 29.

Union Worthington, for thirteen years Chief Surgeon for the Utah Copper Co. and the American Smelting & Refining Co. at Salt Lake City, died at Santa Monica, California, on May 30. He was born at Danville, Kentucky, 59 years ago. He came to Salt Lake City in the early '90s and was associated with Dr. H. S. Pinkerton, Chief Surgeon for the Oregon Short Line. In 1907 he formed a partnership with Dr. A. L. Castleman, and since that time this firm and its associate physicians have had full charge of the medical and surgical work of the Utah Copper and A. S. & R. companies. Last fall, owing to failing health, Dr. Worthington retired from professional practice and moved to southern California. Tuberculosis was the cause of his death. He is survived by his wife and two children.

Frank Allen Keith, prominent mining engineer, died on June 2; his many friends will be shocked and grieved to learn of his death. His professional contemporaries will miss his ability and judgment in the undertakings with which he was associated. He possessed one of those rare, delicate, considerate, and thoughtful natures that makes a large circle of friends without effort—they come inevitably on account of a cheerful, happy, and generous nature. He was anxious that others, especially the younger men, should share in his successes. He was born in 1870, at Detroit, Michigan, the son of John Wallace Keith and Fannie Louis (Allen) Keith. He was educated in the public schools of Detroit and at St. Paul's Academy, of that city. Immediately after concluding his studies he went west, to Colorado, where he became surveyor for the Iron Silver Mining Co., at Leadville. This was the beginning of a life that has been spent in mining and engineering work in Colorado, Utah, Nevada, and California. After leaving the Leadville company, he held successively the following positions: engineer of the Eureka Hill Mining Co. at Tintic, Utah; ore purchaser for the Arkansas Valley Smelting Co. at Leadville; assistant manager, Union Smelting Co. at Leadville; engineer, De Lamar Nevada Mines Co., in Nevada; general superintendent of the Bamberger De Lamar Mines Co.; engineer, Guggenheim Exploration Co.; general manager, Tonopah Mining Co., of Nevada. These firms are among the most important in the mining industry of America, and the offices he occupied have been among the most responsible. He remained in Nevada until 1908, when he moved to San Francisco, where he opened offices as a general mining engineer. After two years he moved to Los Angeles. One of his first mining ventures thereafter was the organization of the Pacific Mines Co., which he managed successfully for a number of years and until its sale to others. A short time later he became interested in Oatman, and through his activity the United Eastern mine was developed and brought to satisfactory production. He resigned the presidency of this company on account of ill health. He was never able to resume his full business activities and during the past few months has been confined to his home. He married Susan Banwell in 1896, at Chicago, Illinois, and there are two children, Frank Allen, Jr., and John Banwell Keith.—S. W. M.

THE METAL MARKET

METAL PRICES

San Francisco, June 7

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	6.75

Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	9.00—9.50

EASTERN METAL MARKET

(By wire from New York)

June 6—Copper is quiet and easy. Lead is inactive and declining. Zinc is dead and lower.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

AIMS OF THE FOREIGN TRADE CONVENTION

The 'Final Declaration' of the Eighth National Foreign Trade Convention, held at Cleveland recently, emphasizes the following as necessary and desirable:

1. Increased imports into the United States.
2. The drawing upon surplus American investment funds in order to furnish long-term credits to foreign buyers.
3. Immediate creation of financial institutions under the Edge Law to extend such long-term credits.
4. Pending the revival of world commerce, the laying up of such of our Government owned Merchant Marine as cannot be chartered on a bareboat basis or on time charter to private operators.
5. Revision of our shipping laws, which subject American vessels to a competitive disadvantage estimated at 5% on the capital investment.
6. Uniformity of State laws affecting marine insurance companies.
7. Adequate international machinery for the enforcement of awards of commercial arbitration; and application of standardization to products not already so protected.
8. Adoption of revised and uniform commercial letters of credit and ocean bills of lading.
9. Maintenance of interest in American foreign trade, even though it shows no profit for the moment; and remembrance that in many cases it will cost much more to regain in the future a business lost now through lack of courage and foresight.
10. A bargaining tariff.
11. A reorganization of the foreign service of our Government, which will provide for unified control and a permanent career to be started at a National Service Training Academy.
12. The passage of the China Trade Act, which will permit the formation of American companies to trade in China on a plane of tax equality with competitors of other nationalities.
13. The change in our taxation laws which will free Americans living abroad from paying taxes upon income derived from within the foreign country of residence.
14. Adequate support for those departments of the Government which participate in the development of our foreign trade.
15. The revision of our revenue laws necessary to permit the negotiation of a parcel-post Convention with Cuba.
16. The wider use of foreign trade news by our press.
17. The expansion of systems of international telegraphic communication under American control and operation.

A BILLION-DOLLAR CORPORATION

Standard Oil Co. of New Jersey made more money in 1920 than any other organization. Its net profit of \$164,481,400 was \$55,000,000 greater than the Steel Corporation and more than \$100,000,000 in excess of Standard Oil of Indiana, the second largest money maker of the Standard group. The New Jersey company does not give combined gross business. However, these can be estimated around \$1,500,000,000. Standard Oil of New Jersey, as at present constituted, is a great deal larger in earning power and assets than the entire old Standard Oil group before it was disintegrated. For the first time the New Jersey company is admittedly a 'Billion-Dollar Corporation'—its assets are given at \$1,102,312,505.

MONEY AND EXCHANGE

Foreign quotations on June 7 are as follows:			
Sterling, dollars:	Cable	3.80	
	Demand	3.81	
Francs, cents:	Cable	8.12	
	Demand	8.14	
Lire, cents:	Demand	4.80	
Marks, cents		1.57	

Eastern Metal Market

New York, June 1.

With Decoration Day on Monday, the business community took a holiday of virtually three days from Friday night, which has accentuated the dullness prevailing in most of the markets.

Interest in copper has subsided, due to various causes; the fall in exchange is a prime factor in foreign sales.

Quietness prevails in the tin market with buying light and prices lower.

Demand for lead is small and there is some pressure to sell from some sources.

The zinc market shows no sign of improvement.

IRON AND STEEL

Buyers of iron and steel continue to act on the belief that lower prices are ahead, and the few current transactions that count at all give encouragement to that belief, says 'The Iron Age'. The old question of the attitude of the Steel Corporation toward concessions made by its competitors is up again in view of some recent transactions in plates, bars, wire, and wire nails. Though there are few products on which prices that went into effect on April 13 are strictly observed, the variations in wire are particularly a matter of comment. The view that price-cutting cannot be effective in a time of low-ebb demand is still held by some important producers; at the same time the Steel Corporation and such independents as have held to the schedule are not expected to 'hold the umbrella' indefinitely.

The railroads are still tightening up as buyers and at the same time intimating that they would buy steel at lower prices. The steel trade is not now so much concerned about lower freights preceding lower steel prices, since it sees both impending.

While the Steel Corporation's schedule this week amounts to 38% operation, independent companies are about 25%. New business is coming to the Steel Corporation's books at a rate below 20% of capacity.

Iron and steel exports in April, at 162,000 tons, were only 40% of the monthly average for 1920, being the smallest month's total in seven years. From the January peak of 647,000 tons the descent seems precipitous, but the January figures represented in part shipments of late 1920 of which statistics had been carried over.

COPPER

A decided lull is in evidence following the confidence which recently pervaded the copper market. This is particularly true of foreign buying which has been the mainstay in recent weeks. Domestic demand is even lighter than at any time lately—if this were possible. The slump in export sales is due largely to the sharp fall in exchange ratios which took place last week. The holiday recess here from Friday to yesterday has been a factor, especially in domestic selling. Prices rule fairly firm at 13.25c., New York, or 13.50c., delivered, for electrolytic for early or June delivery, with Lake copper about on the same levels. It is possible these values could be shaded from some sellers, but there has been no real test. As soon as European conditions settle a little and the holiday spirit has vanished, a better market is expected.

TIN

The feature of the market, if it may be so termed, is the limited number of sellers and their indifference to making sales. The market has consequently been quiet despite a general decline in London. This attitude by sellers has, however, kept the market steady here. Last Friday, the

last day of any recent sales, there were several 25-ton lots of May-June shipment Straits tin sold at 31.75c. and also 50 to 60 tons of spot Straits at 31.87½ to 32.50c., New York. There were also a few sales a day or so earlier at 32.25c., New York. On Friday there was a sharp drop in London, prices falling about £3 per ton; exchange also fell on that day. Yesterday London values were about £7 per ton below those prevailing a week ago, spot standard being quoted at £174, future standard at £175 and spot Straits at £178 per ton. Yesterday in this market spot Straits was quoted at 31.50c. Arrivals thus far in May are reported as 1355 tons with 2380 tons reported afloat.

LEAD

The market is very quiet and slow. The leading interest continues to quote 5c., New York and St. Louis, but in the outside market there is some pressure to sell, particularly at St. Louis, where the metal is offered at 4.70c. for early delivery, the New York quotation being 5c. These offerings are largely speculative accumulations.

ZINC

The market remains lifeless with no signs of improvement. Business is spasmodic and confined to small lots for immediate needs. Some producers continue out of the market at present quotations. Present needs are being satisfied at prevailing quotations which for prime Western are 4.75c., St. Louis, or 5.25c., New York. These could perhaps be shaded to 4.70 or 4.72½c., St. Louis, in some cases and under some conditions, it is conceded.

ANTIMONY

Wholesale lots for early delivery are quoted unchanged at 5.25c., New York, duty paid.

ALUMINUM

The leading producers quotes virgin metal, 98 to 99% pure, at 28c. f.o.b. plant in wholesale lots for early delivery, while the same grade of metal, of foreign origin, is quoted at 22.50 to 23c., New York.

ORES

Tungsten: No business is reported and this market is marking time. Quotations are nominal at \$3.25 per unit for Chinese ores with Bolivian and other high-grade ores at \$4 per unit or higher.

Ferro-tungsten is quoted at 48 to 58c. per pound of tungsten contained in lump form, guaranteed quality.

Molybdenum: Quotations are nominal in an inactive market at 50c. per pound of MoS₂ in 85% or regular concentrate.

Manganese: There is no demand and stocks are piling up with imports at over 60,000 tons per month in the last 10 months. Quotations are nominal at 22.50c. per unit, seaboard.

Manganese-Iron Alloys: There is almost no demand for ferro-manganese or spiegeleisen and quotations are unchanged. American ferro-manganese is quoted at \$80, delivered, and the British at \$75, seaboard. It is possible these prices could be shaded, though re-sale has sold at \$78, f.o.b. seller's plant. Spiegeleisen is inactive at \$30 to \$32 per ton, furnace.

Ferro-silicon, 50%, is quoted at \$80, delivered, with but little demand.

Ferro-vanadium is quoted at \$5 per pound of contained vanadium.

Ferro-chromium can be bought at the regular quotations of 16 to 16.50c. per pound of contained chromium in alloy of 60 to 70% and 6 to 8% carbon.

Wear and tear and the welder

IN no other industry is machinery subject to harder service than in mining and nowhere does a breakdown spell greater disaster.

Modern operators avoid breakdowns by employing the oxy-acetylene process in remaking broken parts, building worn surfaces, welding cracks and similar reclamation work.

Prest-O-Lite

DISSOLVED ACETYLENE

a gas of the highest and most uniform purity, is supplied in readily portable cylinders, particularly well adapted for use in and about mines.

Thanks to the quality of Prest-O-Lite Dissolved Acetylene and the portability of the Prest-O-Lite Cylinder, there is no job of welding or cutting too difficult nor too inaccessible.

Forty plants and warehouses insure a steady and plentiful supply of Prest-O-Lite.

THE PREST-O-LITE COMPANY, Inc.

General Offices: Carbide and Carbon Building, 30 East 42nd St., New York
Balfour Building San Francisco

In Canada: Prest-O-Lite Co. of Canada, Limited, Toronto

T. A. RICKARD, Editor

COPPER SALES in May were the best for any month of this year, the total amount sold being 110 million pounds of metal. Export trade was double the domestic. Most of the buying came from Germany and Japan, with France ranking next.

THROUGH the 'Financial Times', of London, we learn that Mr. Simon Guggenheim, in an interview published by the 'Agence Economique', of Paris, stated that "with complete confidence it can be said that the price of copper has touched its minimum, and that there is every chance in favor of a recovery". This seems to us to be a safe prediction.

ECONOMIC conditions have been reviewed recently by Mr. Hoover, as Secretary of Commerce, in his usual straightforward way and with his usual sane optimism. Conditions are unpleasant, but they might be much worse; they are the logical consequence of causes plainly recognizable. He is confident that "we have fundamentally turned the corner". The last link in the chain of readjustment is the retailer, and it is he that is delaying a return to normal economic conditions and the completion of readjustment "all along the line". For example, we are informed that the beef that fetches, on the hoof, 8 cents per pound is sold by the packers at 16 to 20 cents; thus the packers seem to be profiteering, but obviously not to the same extent as the retailer, who sells the same beef at 40 to 45 cents. Pork that fetches 10 cents in the first instance is distributed by the packers at 23 cents and retailed at 60 cents. If pork chops are ordered in a Pullman diner one pays at the rate of \$1.80 per pound. Sometimes we regret that the Food Administration was dissolved so soon.

ANGLO-AMERICAN amity will suffer as a result of the frank utterances of Rear-Admiral Sims at London banquets and luncheons. His reiterated appreciation of so-called liberty in England—a liberty arising from the fact that the liquor traffic is practically immune from restrictive legislation—is unfortunate when taken in conjunction with other after-dinner indiscretions of speech. Complete liberty in any country is as dangerous as absolute self-determination. The Admiral has been fêted royally; his views on the drink traffic may be harmless as far as his immediate audiences are concerned; but if he should carry his interest in British

social life to the slums of London or Glasgow he would realize that he was treading on dangerous ground, and was incurring a responsibility that ill befits a citizen of a country whose mental, physical, and material vigor is due largely to sobriety. If the Admiral is really so much at variance with the social laws in force in the United States we are inclined to regret his recall by the Secretary of the Navy. We like the stand taken by the American Legion, which has issued a general order to its members, urging them to refrain from engaging in agitation for recognition of the Irish republic. This order was the last official act of Commander W. F. Galbraith, who, most unfortunately, was killed a few days ago in an automobile accident. In part he said: "The national commander is of the opinion that the problem involved is one which pertains to the people of Great Britain and Ireland, and can only be solved by them; that it is not a matter in which the American Legion is concerned, and that members, official posts, and departments of the Legion, as such, should refrain from participating in this agitation, directly or indirectly". Copies of this order should be sent to Admiral Sims, Senator Phelan, and W. R. Hearst. It is inadvisable, if not worse, to permit our national solidarity to be disintegrated by a controversy over a non-American question.

IT has been said of our friends, the British, that they never know when they are beaten. A few years ago Great Britain emerged from the War with a crushing load of debt on her shoulders; but, with the aid of the national attribute of "muddling through" with bulldog tenacity of purpose, the financial situation across the water is showing a slow but steady improvement. This news is of considerable significance to us; for the Atlantic is the most important of our trade-routes, and a condition of chronic financial sickness in Great Britain would soon be reflected in our own industrial life. In introducing the budget recently in the House of Commons, Mr. Austin Chamberlain stated that the sole remaining debt of Great Britain, other than what was owed to the United States and to Canada, was to Sweden, for £826,000, which was not paid because it was not yet due. He stated that foreign debt is the worst encumbrance that any country can be afflicted with. It is a drain upon the national resources; it reduces the purchasing power of the national currency; and it affects world credit. Half of the Anglo-French loan from the United States has

been paid off by Great Britain, at a cost of £51,370,000, Mr. Chamberlain added; this amount, together with other repayments, has reduced, during twelve months, the total debt owing to the United States by nearly £75,000,000. During the two years since April 1919 the external debts of Great Britain have been reduced by no less than £203,000,000. These facts are indicative that John Bull is facing the music with his customary determination; the British government's efforts at financial reconstruction will help to restore stability, not only in Great Britain, but throughout the world.

WORKERS in industrial plants are often thought to be suffering from metallic poisoning, whereas, as a matter of fact, the indisposition arises from another cause altogether. At a recent meeting of one of the branches of the Society of Chemical Industry, Mr. Stephen Miall emphasized the fact that constant exposure to any chemical compound is likely to be injurious to health, especially if dust, fume, or gas is given off; an abundant supply of fresh air is the best provision against illness on the part of the worker. The susceptibility of many persons to the smell of freshly applied paint is well known, and suspicion has been fastened, though insecurely, on the white lead, the oil, and the 'dryers' of which it is composed. It is now considered almost impossible that volatile lead compounds are given off; Mr. Miall explains that the turpentine is the delinquent; kidney disease is caused, and the patient is predisposed to gout. Copper, tin, nickel, and manganese are said to have properties that are injurious to health; but cases of poisoning in the industrial plants that produce or fabricate these metals are few and far between. Lead poisoning in England at one time reached serious proportions; at present, thanks to wise and efficient preventive measures, the number of cases has declined until it is now less than one-tenth of what it was twenty years ago. It can be taken as axiomatic, says another authority, that lead poisoning is caused by the inhalation of dust or fume; in the absence of either there will be no poisoning; efficient ventilation is the essential. Investigations have shown that the minute particles of lead compounds, which may float in the air, reach the lungs of the workers, where they are acted upon by the juices of the body, and so enter the circulatory system. The prevention of dust, or its removal at the moment of formation, the deflection of vapors or volatile solvents, and the substitution of fresh air will, in the opinion of Mr. Miall, reduce the number of cases of painters' colic to insignificant proportions; no other remedy will be as efficacious.

Mexican Affairs

It is much to be regretted that the exchange of views between Washington and Mexico City has not concluded, as had been expected, in the recognition of President Obregon's government by that of the United States. The failure to accord this consideration to the government now established in Mexico is unfortunate because it

renders President Obregon's position more difficult at a time when he deserves the moral support of the United States. The legislatures of several of our States, notably California, Arizona, and Oklahoma, have passed resolutions urging an early recognition of the Obregon government; this action will impress most of our readers more than the fact that several European governments have already done what our own Government has been advised to do. Just now the consummation of mutual goodwill is halted by President Obregon's unwillingness to accept 'recognition' with any 'condition'. On the other hand, Mr. Hughes, as Secretary of State, asks a guarantee that our nationals shall be protected in life and property, and more particularly from such acts of spoliation and confiscation as marked the régime of Carranza. Those who are interested in mining affairs in Mexico will appreciate the need for the stand taken by Mr. Hughes and will be grateful to him for it, while wishing intensely that the diplomatic exchanges may be concluded amicably and with good result. Incidentally, it appears that President Obregon's unwillingness to accept any 'condition' is due in part to the reckless and inaccurate telegram issued by the Associated Press on May 23, in which it was reported that our State Department was about to impose sundry drastic changes in the Mexican constitution as a pre-requisite to 'recognition'. This must have hindered seriously the effort to arrange matters in a friendly way. The gentlemen south of the Rio Grande have national pride like the rest of us and resent not unnaturally any trespass upon their self-respect. Mr. Hughes has not made the mistake, as some of his predecessors in office did, of saying how the Mexicans shall govern themselves or of assuming that our form of government is the one best suited to the Mexican people; he is conducting the negotiations with courtesy as well as fairness, and we hope that a way out of the difficulty will be found. It is greatly to the interest of both the Mexican and the American peoples that they should live in harmony and do business with each other amicably.

Revision of the Mining Law

On pages 865 to 869 of this issue we publish the text of the proposed new mining law, sent to us by Mr. H. Foster Bain, the Director of the U. S. Bureau of Mines, to whom it had been transmitted by the committee appointed by the former director, Mr. Van. H. Manning, on the initiative of the Mining and Metallurgical Society of America. This draft of a new law, and the revision of the old law that it embodies, is the result of the discussion started by the Mining and Metallurgical Society eight years ago. Mr. H. V. Winchell took a leading part in guiding this discussion, being moved thereto partly by his general knowledge of apex litigation and partly by his own personal experience in Alaska, where he suffered what he, and most of us, considered to be an injustice in consequence of the unfair incidence of the existing law. In 1914 the Society issued a questionnaire on the subject and elicited the views and votes of a number of repre-

sentative metal-mining organizations in the United States. In 1915 a special meeting of the Society was held at Washington; to this were invited the representatives of many organizations, to whose attention the subject had been brought by means of the questionnaire of the previous year. At the meeting it became evident that there was a strong sentiment in favor of the revision of the law, especially in respect of the extra-lateral right and the requirement of discovery before location. Mr. W. R. Ingalls, who was then president of the Society, took a leading part in these proceedings. An effort was made to induce Congress to appoint a commission to take testimony on the subject, but members of Congress suggested that those engaged in mining, more particularly the engineers, should submit their views, to which prompt and definite consideration would be accorded. The Mining and Metallurgical Society, which, by the way, consists of a small and select number of engineers and geologists, most of whom are also members of the American Institute of Mining and Metallurgical Engineers, was unwilling to undertake the task, recognizing the need, *inter alia*, of legal advice in formulating any legislative enactment. Moreover there had been a feeling at Washington that some of the engineers represented private interests, and the knowledge that such an idea existed was enough to make them "loath to devote further time to the subject unless sponsored by some individual or organization which was above possible suspicion of an ulterior motive". We quote from Bulletin 140 of the Mining and Metallurgical Society. An *impasse* seemed imminent when Mr. Ingalls and Mr. Manning conferred with a view to preventing a failure of so much well-meant effort, and it was arranged that the Bureau of Mines should appoint an advisory committee to be nominated by the Society, "and furnish the legal talent necessary from its own staff". Thereupon, on January 23, 1917, Mr. Ingalls was appointed chairman of this committee, with Mr. Walter Douglas as vice-chairman. The other members were Messrs. J. Parke Channing, J. R. Finlay, John Hays Hammond, Hennen Jennings, and L. D. Ricketts. Mr. Winchell could not serve because he was about to go to China; but on the decease of Mr. Jennings, in March 1920, he joined the committee. Mr. J. R. Jones, law examiner for the Bureau, was appointed secretary and legal adviser. Later he was succeeded by Mr. Paul S. Black as solicitor of the Bureau. During the War not much could be done; but, since the Armistice, Messrs. Jones and Black have studied the discussions, the results of the referendum, and the questionnaire, and have prepared a draft, which "harmonizes the majority of views as expressed during the past few years with such parts of the existing code as appears most desirable to retain". Again we quote from the Society's bulletin. This draft was submitted to the committee and is now in the hands of the House and Senate Committees on Mines and Mining, the chairman of these co-operating in making such further changes as may be found desirable after discussion in Congress.

In our last issue, under 'Review of Mining', we quoted

at length from the report presented by Mr. Ingalls, as chairman of the Committee on Revision, to the Director of the Bureau. In that report Mr. Ingalls gives an admirable summary of the proposed law, and our readers will find that summary useful in giving them both an outline and an explanation of the proposed Act. It will be noted that whereas the principle of extra-lateral right is abolished, the requirement of discovery is retained in a modified form as a condition precedent to the obtaining of a patent on a mining claim. The area covered by a location is to be nearly double that staked under the existing law. The lines of all claims must conform to the subdivisions of the General Land Survey and are oriented with reference to the cardinal points of the compass, instead of being irregular as at present and making intersections, overlappings, and complexities. It may seem that rigid compliance with this regulation will be impracticable in a new region; even if every prospector be supposed to carry a compass, he may not know the magnetic variation in the locality of his claims. The requirements of assessment work are changed, so that a payment of \$5 per acre may be paid directly in the nearest Land Office in lieu of work done on the claim; and this money is to be set aside as a special fund to be used for the purpose of "developing the mineral resources" of the mining district in which it is collected. The spending of the money is left to the Secretary of the Interior. In order to provide space for the storage of tailings, and other material now discarded but likely to prove of economic value in the future, by reason of improvements in metallurgy, it is specified in the Bill that adequate areas of public land shall be purchasable for this purpose. Evidently the whole matter has been considered carefully and by men who have given much thought of it. We find some of the wording awkward and some of it obscure, but these defects will be remedied by the legislative committees. Meanwhile we shall be glad to hear from our readers; it is highly desirable that public opinion be expressed on both the matter and the manner of the proposed law, which necessarily will play an important part in the further development of our mining industry.

Simplicity in Metallurgical Planning

Complication in the planning of metallurgical processes should be avoided at all costs. An expert consultant, with a wealth of ideas, may design the plant; but the man who has the task of operating it is provided usually only with a brain of normal size and character; he is helped by assistants and laborers, each of whom has only two hands and two feet; the majority of operators are accustomed to practice, but they usually balk at theory. If the designer had to operate the plant he would, in many cases, make a greater effort, during the preliminary planning, to avoid complications; simplicity should be the primary aim of every constructional engineer, for by it accuracy is made more nearly obtainable. The unnecessary is avoided. These comments are made

as we call to mind the fate of an enterprise that depended for its financial success on an elaborate scheme that was to be put in practice in a foreign country, and far from home. Under such conditions it should be realized that simplicity is all the more desirable: repair parts often are difficult to obtain, and skilled labor usually is scarce. The equipment was exceptionally complete; everything that money could buy was requisitioned by the consulting engineer. The plans and reports were so complicated with figures and charts that, although additional professional advice of a most expensive kind was obtained before the final acceptance of the scheme, the unfortunate sequel was never anticipated. The plant was erected. A section was made to operate with comparative ease, but the engineer in charge of the operation of the plant had no faith whatever in the scheme of treatment, and he said so. So far as human endeavor could go, he and his assistants worked to achieve satisfactory results, but all their efforts were in vain. At length, after an emphatic statement of the facts had been forwarded to the head office of the company, the governing officials of the enterprise decided that the designer of the plant should be given an opportunity to prove the process. This was done, and he was provided with as many assistants as he needed. The plant was re-modeled and re-arranged, at considerable expense, but it still remained hopelessly complicated. The engineer's assistants were loyal and hard-working; after a few months, all concerned became physical wrecks, but a measure of success was obtained—a portion of the material was treated with good results; the remainder, however, refused to dissociate itself in the proportions and in the directions that were anticipated in the flow-sheets. After some months of useless and profitless expenditure it was realized that the scheme, as viewed from the economic aspect, was a complete failure; with expert help and at considerable cost it could only be made to show a small measure of technical success. The plant was at last closed down; the machinery was sold for what it would fetch; the money that should have been used for furthering research work of a promising nature had been wasted. In some respects the operation had been successful, but the patient died. The treatment involved too many complications.

The Japanese Problem

Herbert Spencer's opinions with regard to the possible admixture of the Eastern and Western races were used with telling effect by Senator James D. Phelan, of California, in a speech made before the Senate recently. It appears that when Japan organized her government she asked Spencer, who was considered one of the greatest economists of his time and an accepted authority on such subjects, whether foreigners should be admitted. "Emphatically, No," was the reply. Spencer then wrote a letter to the statesmen of Japan, stipulating that it should not be published until after his death; and in it he advised the Japanese to grant to foreigners only bare commercial privileges, to forbid them to own lands, to

hold them at arm's length, and to make no attempt at intermarriage, because, he averred, it is impossible biologically under such circumstances to produce a race that will not be of a deteriorated type. He instanced the half-castes, the mestizos, the mulattos, and the mongrels of other countries. In most cases, nationals of different types, each good within his limitations, have been ruined by the attempt at amalgamation. Thus it is impossible to consider the Japanese as coming to our country for the purpose of assimilation; and they know it. They themselves have refused to foreigners all the privileges they ask of us; they have granted them, as they were advised by Herbert Spencer, only bare commercial privileges; and this has been to their great advantage, for they have preserved the purity of their race. In the arts and in manufactures they are successful, and as a fighting people they rank with the best.

Spencer entirely approved the regulations that were established in the United States for restricting Chinese immigration, which was a much older problem than the one we have now with Japan. The Chinese were excluded in 1879; the Japanese did not begin to arrive until about 1885; and then they came by way of Hawaii; they were permitted to settle where the Chinese had been barred. Writing on the subject of Chinese immigration, Herbert Spencer showed that if these foreigners were allowed to settle extensively in the United States, a bad hybrid would result, or they would remain unmixed. In either case, supposing the immigration to be large, immense social mischief would result, leading to disorganization. The Japanese in the United States remain unassimilated. Japan followed Spencer's advice to the letter; and, as Senator Phelan says, when we bar the Japanese from the land, when we restrict Oriental immigration, we are acting exactly as Japan herself is acting: it indicates a policy that has been successful in Japan during the past half-century; she will not admit Koreans nor Chinese when either competes with her own people; and she is wise. We too want no settlers in this country who cannot be assimilated, and assimilated readily into the great American family; and this is the fundamental reason why California does, and why the United States as a whole should, object to Japanese immigration. The test of the entire desirability of any type of immigrant is that the alien, on examination, and after a residence of a few months or a few years, as the case may be, can be considered, by an impartial tribunal that knows nothing as to his country of origin, as an American—first, last, and all the time—in speech, habits, and in his community life. There are degrees of fitness for citizenship, but ability to assimilate quickly and to become a typical American is the primary essential. If the immigrant retains a too fervid adherence to the people or the customs of the land of his birth, and shows it, he will not make an ideal citizen; if his children are encouraged to speak a foreign language, if they are taught to preserve an alliance to foreign ideals and to foreign traditions, then he and his type are undesirable, for assimilation is impossible.

DISCUSSION

Gold in Black Sand

The Editor:

Sir—Probably a treatment suitable to one locality would be unsatisfactory when applied in another. The richness of black sand is as variable as its components. In working vein-ore the results from the mill and from the concentrates are not a constant, and the richness of black sand differs materially even in a few feet. I have carried out a number of perhaps rather crude experiments, but believe the results may be useful to some of your readers. I have concentrated down to the nearly clean black sand, and I found much less gold in it than when a considerable proportion of the heavy gray and brown sand was left in. After amalgamation, I separated the concentrate magnetically—the non-magnetic averaging 35 to 40% of the original. By grinding the magnetic, I find it releases about 10% more of the non-magnetic—by various tests, which need not be specified. I obtained practically no value out of the magnetic material. By roasting the non-magnetic portion to cherry red and then grinding it, I get values in gold ranging from roughly \$50 to \$800 per ton that can be amalgamated. Grinding alone without roasting gives a good return, but roasting increases it. I find that by grinding a sample without magnetic separation, extraction is considerably reduced, and is reduced by about 80% if the non-separated sample is roasted. I speak, of course, of recovery by amalgamation. As about 20 lb. of this non-magnetic sand can be recovered here per cubic yard of gravel it is an important asset. My conclusion is that every large placer proposition 'contaminated' with black sand, should have a concentrator, an electro-magnetic separator, and a ball-mill as part of its plant, and where platinum is present, a complete chemical outfit may also be necessary.

Rogue River, Oregon, May 24.

The Strike at Tonopah

The Editor:

Sir—In your issue of May 28 is an article regarding conditions in Tonopah. Whoever gave you this information has garbled the truth to such an extent that we thought possibly the real conditions might receive your attention also. It is true that 25 to 30% of the number of men employed before the walkout are still working, but their wages were not cut. They are working at the old scale. Not one has gone back to the mines where wages were reduced. The operators have brought in quite a

number of boys and men on several occasions, and nearly all of the first two bunches deserted upon arrival here. The others are of no value as mine or mill-workers.

The rails of the T. & G. Ry. Co. were greased by someone and the miners are making a thorough investigation to find out who is guilty. The street talk is to the effect that the operators caused it to be done in order to create an unfavorable impression in the public mind. They have been unable to incite the men to violation of the law so far. The big gambling houses are closed and there is no drunkenness or disturbance of any kind, owing to the fact that we have a level-headed sheriff who tends to his business and takes orders neither from the men nor the operators.

If the operators made the wage-cut with such arbitrary suddenness in retaliation of some fancied violation of an agreement, they have repented of their act at leisure and will continue to do so; however, they have seen a great light and the chances are that the camp will soon be going again in peace and prosperity, and we feel that they will not soon forget the lesson they needed.

I trust you will be as liberal in publishing the version of those who really produce the gold and silver in Tonopah as you have been to those who furnished the misinformation published.

HARRY BUTSON,
Chairman Mine and Mill
Workers Committee.

Book-Reviewing

The Editor:

Sir—The criticisms called forth by A. W. Allen's reviews on Slosson's 'Creative Chemistry' and Soddy's 'Science and Life' are not without interest, though I do not agree with either critic. P. B. McDonald's view that, because a book is a prodigious work and on the whole is sound, only its praises should be sung and its minor flaws should be overlooked by the reviewer is, to my way of thinking, untenable; nor do I believe such leniency would be appreciated by the author. Herbert Spencer complained of what the critics left unsaid, rather than what they said about his books. To spend years of toil—pleasant toil, perhaps, but nevertheless toil—on a book, and then to have it reviewed only in the barest outline, with a pean of praise added, surely would be far more disheartening than to have it intelligently, even if ruthlessly, reviewed; and evidently Spencer so thought, for in his autobiography he reviews several of his own books at considerable length; and, having built the structures and knowing their weak points, he did not fail to

indicate their weaknesses, for the purpose of showing how reviewers might have made constructive criticism. H. G. Wells, too, in his 'Outline of History', evidently appreciates the criticisms of his collaborators, for a bombardment of such, in the form of footnotes, accompanies the text. Only by such constructive criticism can perfection in future editions be approached.

Turning to the Austin criticism of the review of 'Science and Life', and comparing it carefully with the review itself, I fail to see that Mr. Allen can be accused of undertaking "to strike at religion over the Professor's [Soddy] shoulder". He entirely fails to make the point. I take issue with Professor Austin, too, when he says: "I can assure Mr. Allen that a generation ago when Darwin's views on evolution were pressed to the limit, scientific men were cocksure they were right". If there were any cocksureness about the controversy at that time it did not come from the scientists. Huxley, as soon as he had read the 'Origin of Species', constituted himself as the champion of Darwin's views, and never tired of reiterating his opinion that he considered it to be the best working hypothesis that had been offered; but seldom did he fail to point to what he believed to be one great weakness of the theory: the infertility of hybrids. This he believed some day might be elucidated. Scientists of a generation ago did not consider Darwin's theory a finality, nor do scientists today; but, like those of a generation ago, scientists of today consider it the best working hypothesis that has been offered; and a good many theologians have come around to the same way of thinking. That Huxley considered belief in evolution to be compatible with belief in a God—not necessarily the God of Abraham, of Isaac, and of Jacob, but of a God—is evident, for he was too great a hater of humbug to have chosen the following lines (from one of his wife's poems) to be engraved on his tombstone, had he not believed in a deity:

"Be not afraid, ye waiting hearts that weep,
For still He giveth his beloved sleep;
And if an endless sleep He wills, so best."

Moonshine Power

The Editor:

Sir—In the 'Press' of May 21, bottom of page 702, you state, "the earth underneath the water being subject to a less attraction because of greater distance".

Therefore, take a deep mine shaft with a strong head-frame and sheaves with proper ropes suspend two boxes one above the surface, the other at a suitable depth in the shaft. Fill the boxes with suitable weights until they balance each other, then add enough additional weight until the upper box will just lift the one in the shaft. Now when the moon comes to the zenith it will attract the box on the surface, the shaft box not being subject to this attraction will sink causing a rotation of the sheave-wheels.

According to your article the moon lifts the water

1.34 ft., which would mean it lifts about 80 lb. per square foot, unless the tensile strength of water 52 grammes per square centimetre causes the lift of 1.34 to be less than with no tensile strength to water, the surface box need not weigh over 80 lb. to the square foot; the shaft box can be of any shape.

Leaving out the sun, then about twice a day the surface box will rise causing the sheave-wheels to rotate; attach a dynamo to sheave-wheels and you will have moonshine! The power produced will, of course, be: lift in feet \times 80 \times area of box in square feet, minus friction, divided by half of 1419, which will give the effective foot-pounds per minute.

I have not as yet calculated how high the box will lift but any astronomer can work it out.

Philadelphia, May 27.

R. H. SANDERS.

[Had our correspondent read the editorial in question a little more carefully he would have seen that the tidal rise of 1.34 ft., due to lunar attraction, was the result of an observation made in the centre of the Pacific area, where there would be difficulties in the way of obtaining a foundation for the apparatus described. Our correspondent does not appear to have selected a suitable avenue for research.—EDITOR.]

Russian Placer Mining

The Editor:

Sir—In your issue of April 30 I was pleased to read a letter from G. L. Holmes in criticism of Mr. Perret's article that you had recently published. Mr. Holmes is correct in maintaining that the electric-dredge possesses superior qualities to a steam-dredge, as I will show later by figures of actual results obtained at Kolchan. Mr. Perret is hopelessly wrong in most of his references to Kolchan; in the first place, there are not two electric-dredges, but one steam-dredge and one electric-dredge, and the power-station does not consume 10,000 to 15,000 cu. sag. per season: 1250 cu. sag. being about the average figure.

During two consecutive seasons, the results of the two dredges of the Orsk Goldfields company as regards fuel consumption and yardage were as follows:

	Cu. sag. wood consumed	Cu. yd. dredged	Cu. sag. wood consumed	Cu. yd. dredged
Electric	1391	730,515	1268	788,306
Steam	1263	137,773	906	105,080

Though the steam-dredge has much smaller buckets and operates under rather more difficult conditions, those disadvantages cannot account for the fact that the electric-dredge accomplished more than five times the yardage per unit of fuel consumed than the steam-dredge does. Your correspondent, Mr. Holmes, will no doubt be amused at the way Mr. Perret's arguments collapse when the truth becomes known. It is to be hoped that the rest of Mr. Perret's article contains no other misleading statements, like some of those he has made concerning Orsk Goldfields.

S. J. SPEAK.

London, May 20.

THE MINE AT CHUQUICAMATA

The Chuquicamata Enterprise—II

By A. W. Allen

To speak of the moving of a mountain is to be reminded of the school-boy's definition of faith as "the quality that enables you to believe what you know to be untrue". Faith in the ultimate success of the work at Chuquicamata, where a mountain is being moved without fuss, was, necessarily, an important asset; but the application of science, by men of courage, skill, and experience, was the dominant factor that ensured the fruition of plans on an ambitious scale.

Few more striking examples of the natural blending of colors can be seen than at Chuquicamata. From across the gully a panorama of broken and exposed rock meets the eye. At the time of my visit, some extensive showings of bluestone gave an intense coloration to sections of the faces; in the distance there blended the green of the brochantite and the atacamite with the blue of the chalcantite—all mixed with yellow and reddish iron stains. In addition to brochantite ($\text{CuSO}_4 \cdot 3\text{Cu}(\text{OH})_2$), atacamite ($\text{Cu}_2\text{ClH}_3\text{O}_3$), and chalcantite ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$), there are a number of rarer minerals in the deposit; these include krönite ($\text{CuSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$), an azure-blue mineral, and coquimbite ($\text{Fe}_2(\text{SO}_4)_3 \cdot 9\text{H}_2\text{O}$), a soluble mineral occurring in a number of colors that vary from white to green. Other unusual minerals are blödite ($\text{MgSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$), colorless to brick red; fibro-ferrite ($3\text{Fe}_2\text{O}_3 \cdot 2\text{SO}_3 \cdot 10\text{H}_2\text{O}$), and copiapite ($2\text{Fe}_2\text{O}_3 \cdot 5\text{SO}_3 \cdot 18\text{H}_2\text{O}$), two types of yellow minerals that are found near Copiapo, from which the latter-mentioned one takes its name; mirabilite ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$), melanterite ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$), jarosite ($\text{K}_2\text{O} \cdot 3\text{Fe}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 6\text{H}_2\text{O}$), and alunite ($\text{K}_2\text{O} \cdot 3\text{Al}_2\text{O}_3 \cdot 4\text{SO}_3 \cdot 6\text{H}_2\text{O}$). In the sulphide zone the principal copper minerals are cupriferous pyrite (CuFeS_2) and enargite ($3\text{Cu}_3\text{S} \cdot \text{As}_3\text{S}_7$), together with chalcocite (Cu_2S) and covellite (CuS).

There is no sharp line of demarcation between the ox-

idized and the sulphide zones. The mixed zone at Chuquicamata is of considerable extent, the ore-reserves in this part of the mine amounting to over 150,000,000 tons of an average copper content of nearly 3%. No method of treating this mixed ore has been formulated as yet, nor is the question likely to be considered until an appreciable effect has been made on the immense tonnage of material that is now available and that contains easily soluble copper minerals. Water level occurs along a plane, which is independent of the existing topography, at a depth that varies from 270 to 800 ft. below the ground, the average being about 600 ft. Water level is usually in the mixed-ore, but occasionally in the oxidized-ore, zone; in only one case was it found to correspond with the line of demarcation between the two zones. A steady decrease in the amount of oxidized ore occurs at depth; chalcocite is met with first, then a mixture of chalcocite and primary sulphide, then primary sulphide only.

A small amount of the ore that is milled is broken by means of powder blasting with churn-drill holes, the greater proportion by far being obtained by the shattering of immense bodies of rock by the explosion of large amounts of powder in tunnels that are driven in lines parallel to the working face. Mining at Chuquicamata is an illustration of rock being broken on a vast scale, on a larger scale than in any other part of the world. The tunnel floor is driven at a level about three metres below the bench on which the steam- or electric-shovels operate, in order to be sure that loose rock is always in the path of the dipper. The height between benches is taken at 45 metres and the horizontal distance between blasting tunnel and face, 30 metres. Entrance to the tunnels is by means of shafts and cross-cuts. The distance between blasting-tunnels depends on the height of the orebody; for a height up to 75 ft. the tunnels are driven so that

the centre-to-centre measurement is 15 metres; for a height between 75 ft. and 100 ft. it is 22.5 metres; for a height over 100 ft. it is 30 metres. The tunnels are 2 metres high and 1.5 metres broad. The amount of powder used depends on the character of the rock in the immediate vicinity, the height of the orebody, and other varying features. Factors are used in connection with the work, with the result that a scientifically accurate

BLASTING-DIAGRAMS

Method of loading tunnels (top); method of wiring tunnels (centre); arrangement of powder, dynamite, and leads (left-hand, bottom); effect of varying amounts of explosive (right-hand, bottom).

estimation can be made beforehand as to the results of any explosion.

It has been found that there is a limit to which economy in the use of powder can be carried. By reducing the quantity, the ground is merely broken, and remains, to a large extent, *in situ*; an adequate amount of explosive will cause a disintegration of the whole mass—the force of the explosion will throw it forward in the form of a billow. Thanks to the use of the factor already mentioned, and the intelligent control of operations in other directions, it is possible to anticipate to

within a few feet the line at which the ore will extend after the explosion. Track moving is, therefore, considerably simplified. The disintegration of the mass is also more complete; shoveling costs are reduced; the bench is worked more easily because the ore does not hang at a dangerous angle. The increased cost of powder, when an adequate amount is used, is more than counterbalanced by decreased expense in handling the rock. Whatever the amount of explosive used, however, a proportion of large boulders results; these have to be broken down with Jackhammers and blasted separately. The original estimate of primary breaking at the plant was, as has been mentioned before, defective; larger machines had to be installed to handle the boulders.

The powder used in blasting is made locally, the composition being 75% Chilean nitrate, 15% charcoal, and 10% sulphur. The mixture is stacked in 100-lb. sacks in the tunnels, the amount used in any particular place depending on the factor already mentioned. Boxes of 40

THE RESULT OF A BLAST

or 60% dynamite are placed in the centre of the charge in amount equivalent to about 2% of the weight of the powder to be used. The tendency has been to reduce the distance between charges; a centre-to-centre measurement of 10 metres was customary in earlier operations; but the distance has now been reduced to 8 or even 6 metres. Electric exploders are used. One box of dynamite is arranged with a hole in the side for two leads, connecting with detonators and sticks of dynamite; the two (No. 7) exploders in each charge are connected with separate circuits. A circuit must not exceed over 3000 ft. in length; for four circuits a 2-kw. alternating-current single-phase transformer is necessary to reduce the voltage to 110; for a larger number of circuits a correspondingly larger transformer is used. All the exploders in the circuit are connected in series; a maximum of 18 exploders per circuit is maintained. The lead wires are of 14 gauge (B. & S.); these are laid in $\frac{1}{2}$ -in. grooves in a 2 by 4-in. stringer, which is then covered with a 1 by 4-in. strip. Against each side of the charge of powder in the tunnel a wall of sacks containing stones is built; the intervening space between the sacked-stone protecting

wall is filled with waste or ore.

Details of a comparatively recent charge (No. 42), by which the effect was achieved entirely by tunnel blasting, without the use of auxiliary drill-hole blasting, were as follows:

Length of tunnels, metres.....	204
Black powder used, lb.	363,500
Dynamite used (40 %), lb.	5,850
Ore broken, tons	740,270

A considerable amount of research is being carried out with regard to the best method of firing. To date all charges have been fired simultaneously; but with added

accompanying halftone and line drawing; in the latter, the dotted line represents the angle of repose of the broken rock after a cushion shot; the heavy line, corresponding to the effect shown in the photograph, is the result that is obtained after the use of an adequate amount of explosive. Tunnel blasting has almost entirely superseded churn-drill blasting at Chuquicamata, the latter method only being used under special circumstances, and for small work. As may be imagined, there are no misfires in tunnel blasting, and this indicates an important item of superiority. The cost of breaking is also considerably less.

A 225-B BUCYRUS ELECTRIC SHOVEL AT CHUQUICAMATA

experience, aided by the study of motion pictures, the officials are of the opinion that quick-series blasting may be preferable. In this event the switch connecting the electric detonators with the source of current may be arranged somewhat after the construction of a rheostat, the various charges comprising the blast being fired in quick succession, almost simultaneously. By a mechanical operation of the switch, the time intervals between the explosion of individual and contiguous charges may be adjusted to a nicety, the result being in the nature of a *feu de joie* on an imposing scale. It seems probable that an economy in explosive may be effected by the adoption of such a scheme.

The advantages of the present method of blasting as compared with cushion shooting is well shown in the

Removal of the broken ore from the bench is effected by means of electric- or steam-shovels of various kinds. The electric-shovel is preferred because of greater ease of manipulation, cleanliness, and lower operating cost; these factors more than counterbalance the increased first cost of the machine. The largest shovel on the property, a 225-B electric Bucyrus, is shown in the accompanying halftone, the photograph for which was taken from the bench above. The dipper is of 6-cu. yd. capacity.

The ore is transported to the mill in large cars, originally designed for bottom discharge; these are hauled by standard American locomotives. Ore and car weigh 90 tons; ore alone, 68 tons. The cars, on reaching the crusher-station, pass into a special type of tippie, which locks the car, elevates it about 30 ft., turns it completely

over, and tips the contents on to one of two grizzlies, which precede two 84 by 60-in. jaw crushers, made by the Power & Mining Machinery Co. Each of these machines has a capacity of about 1200 tons per hour, crushing to

pletely the dust that is produced would result in a considerable amount of action on iron and steel.

The swinging-jaw breakers are operated by a rope drive from electric motors. The crushed ore, together

SMALLER ELECTRIC SHOVEL LOADING CARS

CAR TRAIN WITH STANDARD LOCOMOTIVE

about 10 in. Spraying to reduce dust is practised, a hose being used, as shown in the accompanying halftone; but the amount of water must be strictly limited. The copper minerals are so soluble and the resultant solution is so corrosive that the use of sufficient water to allay com-

with the undersize from the grizzlies, drops to a 48-in. belt-conveyor, on which it is conveyed to the primary ore-bin, which has a capacity of 13,000 tons. The discharge of the 48-in. belt-conveyor is distributed throughout the ore-bin by means of a 48-in. shuttle-conveyor.

CAR-TIPPLE AT THE CHUQUICAMATA PLANT

The crushed ore is drawn from the ore-bin by means of 16 pan-feeders delivering to three 36-in. belt-conveyors. Each belt-conveyor discharges over a grizzly, the over-size of which goes to a McCully crusher, where it is reduced from 10 in. to 3 in. The crushed and screened ore is delivered to three 36-in. belt-conveyors, over which three stationary mushroom magnets are hung, for the removal of tramp iron and steel. The ore again passes over a grizzly, after which it is fed to eight 48-in. horizontal-disc Symons crushers, which reduce it to 1½ in. The final crushing is done in twenty-four 48-in. vertical-disc Symons crushers, the leaching product containing about 12% of material that will rest on a 0.371-in. screen. A typical analysis of the material that goes to the leaching vats is as follows:

Mesh	In.	%
On	0.371	12.6
" 8	0.093	56.5
" 100	0.0058	8.1
" 150	0.0041	17.3
" 200	0.0029	1.8
Through 200	0.0029	3.7

The small amount of fine material produced during crushing is an evidence of the logic in arranging stage crushing so that each type of machine has a comparatively small amount of work to do, as judged by mass reduction and not by capacity. Rolls refuse to operate when expected to effect a large reduction in particle-size; they can be operated at a low efficiency when reduction ratio is considerable; they work well when called upon to effect a reduction in the ratio of about four to one. Other machines, like the ball-mill, can be made to produce a finished product in one operation; but the result is usually uneconomical. In large-scale operations, as at Chuquicamata, the success of leaching is largely due to the fact that so many machines are necessary, in any case, that reduction in particle-size in several stages is more practicable than in the case of smaller enterprises. The moral, however, is the same in every case. The simplicity resulting from a restriction in the number of stages of crushing is more than offset by the actual mechanical inefficiency of crushing and the undesirable character of the product.

The dusting problem, in and around the fine-crushing plant, is a serious one; much discomfort results from the acidity of the particles on the mucous membrane of nose and mouth, and operations are rendered increasingly difficult. Masks are worn but the evil is not cured thereby. The rapid conveyance of immense tonnages of crushed ore necessitates an unavoidable amount of dusting, which cannot be avoided. Much has been accomplished in reducing the nuisance by enclosing the secondary crushers as much as possible. No system of vacuum abstraction of dust would appear to be feasible. The changes that have been made in the crushing department are principally in connection with the substitution of Symons disc-crushers in place of the high-speed rolls that were installed originally. Experiments have been made with the idea of using mechanical screens before the ore reaches the final crushers. This would doubtless

serve to by-pass a proportion of the material that at present goes to the crushing plant, and so reduces capacity. The dusting problem, however, is one that may detract from the practicability of the scheme.

An elaborate system of cross-conveyors is used to carry the ore to the leaching-vats, three Vezin machines being used to cut a final sample of about 400 lb. from each charge of 10,000 tons, or thereabout. The main conveyor, 36 in., which runs along the length of the leaching-vats, has a rise of about 12 feet and trips on to the filling-belt, also 36 in. wide. This filling-belt delivers con-

SPRAYING THE ORE AS DISCHARGED ONTO THE GRIZZLEY THAT PRECEDES THE CRUSHER

tinuously across the vat and has a traveling tripper that ensures the even discharge of material into the vat, as shown in the accompanying halftone. The time taken to fill a vat is usually between 12 and 14 hours. A Merrick weightometer is used to determine the tonnage.

The leaching-vats are constructed of reinforced concrete, and are mounted on piers that are set above the ground; rubber expansion joints are used. The insides of the vats are lined with a mastic mixture made of 75% sand and 25% (mixed) asphalts, the latter being manufactured by the Barber Asphalt Paving Co. The floor of the vat is merely covered with this mixture; the sides are first covered with a layer of expanded metal, into which the asphalt mixture is afterward embedded. Six of the original vats in the plant were 150 ft. long, 110 ft. broad, and 16 ft. deep; the depth has since been increased to 17½ ft., which gives them a capacity of well over 10,000 tons per charge. Three newer vats are of the same length and width, but have a depth of 19 ft. 6 in.;

vats to be constructed in the future will be of this depth.

On the mastic floor of the vat are laid timbers, each 6 by 6 in., and spaced at 18-in. centres. These are sawn out on the under side, to allow for the free passage of solution in the direction of the exits. On these bearers is placed a grid of 2 by 6-in. planks, spaced $1\frac{1}{2}$ in. apart, coco-matting being laid on this. The shoveling-slats are also of 2 by 6-in. material; they are laid flat and at right angles to the grid planks, and are spaced about $\frac{3}{4}$ in. apart. No particular care is taken in the laying of the coco-matting, or in caulking at the edges. A proportion of dead ore is allowed to remain in the vat and is not removed by the grab-bucket. There is so little resistance

the possible utilization of a permanent sand bottom. I introduced this method of bottom construction several years ago at a cyanide leaching plant that was equipped with 200-ton vats, but I do not know if it has ever been tried on anything like so large a scale as the vats used in copper leaching at Chuquicamata or Ajo. In the smaller vats it worked excellently. With the larger plant it might be suggested that the bottom of the vat should carry the 6 by 6-in. timbers, arched underneath to facilitate solution flow. These bearers would be spaced as required, and would act as a support for other timbers of the same size, placed crosswise and on top of them, and in the line of action of the grab-buckets. These, too, would

A 10,000-TON LEACHING-VAT BEING FILLED

to the flow of the solution, thanks to the filling of the vat by automatic methods and the even distribution of fine ore, that the chance of a short-circuit of slimy solution is unlikely. The actual area of percolation represents no more than about 11% of the area of the vat bottom; this will give an idea of the ease with which leaching is carried out. At the same time, it compels attention to the fact that only a negligible proportion of the coco-matting in the vat is utilized; about 90% lies underneath the shoveling slats; it rots there, and has to be replaced about every five years. The cost of treatment at Chuquicamata is so low, on account of large-scale operation and efficient control, that if all the expense of the coco-matting were avoided, the net result per ton would be negligible. There is, however, the question of the cost of labor in replacing the bottoms; and on this account I had the temerity to suggest to the manager

be spaced, as are the present shoveling slats, to allow for the percolation of the solution. The spaces between the timbers would be filled with stone, gravel, and sand, of graduated sizes, and arranged so that each smaller size would pack on top of, but without falling through, the size larger below. The class of material to be used for the surface layer would depend on the composition of the charge being leached. A fairly coarse sand would be feasible in most cases. It would seem that such a bottom, when once laid and laid properly, should be as permanent as the bottom of the vat. Care, of course, must be taken that the shoveling slats are not shifted during the operation of the grab-buckets; but otherwise I can see no obstacles against practicability.

The point that is not generally understood in leaching work is that the bottom, if it functions properly, does not act as a filter. If that were its function it would choke

almost immediately after downward leaching were commenced; or a muddy solution would appear underneath. The function of the bottom is to offer an adequate support for the charge, preventing any movement whatsoever of solids in the direction of solution flow; it allows for the even distribution of solution during upward submergence of the ore, thus obviating channeling; and it permits the efficient drainage of the charge at the conclusion of leaching. The use of the term 'filter-bottom', as a designation of the support for the charge in a leaching-vat, has led to a great deal of misconception on the subject; I am sorry to say that I only realized this fact recently. The coco-matting or sand does not act as a filter in any way. Clear solutions can be obtained by leaching under proper conditions and whether upward or downward percolation is being practised. The solutions drawn from the top of a charge are almost as clear, assuming correct operation, as the solutions that are drawn from underneath the bottom support; no filtration occurs on the surface, obviously; and none is necessary along the plane of the bottom support. The actual amount of slime in contact with the bottom support is infinitesimal; if the charge is properly proportioned and the rate of percolation is normal, then no more should be carried there by the solution.

Each leaching-vat at Chuquicamata is equipped with eight 6-in. drain pipes; these are fixed in the bottom and are caulked with hard lead; they converge to a large main drain that goes to the pump-house. A good deal of experimentation has been carried out with regard to the best class of piping material to use. Lead-lined iron was first adopted, but this has been superseded partly by pipe that is made of asphalt mastic and partly by wood pipe, the outside of which is protected by a coating of tar.

The accompanying halftone gives a good idea of the method of filling, as well as the billowed appearance of the top of the vat when full. A small amount of segregation occurs during the filling; this is intentional; a small proportion of large gravel slides down the natural slope that is formed, and a bed is made at the bottom, on which the charge rests. However, as seen from the screening analysis quoted previously, the amount of true slime in the ore is exceedingly small, the proportion of material that would pass through a 200-mesh screen being under 4% of the weight of the charge; and through a 150-mesh screen, less than 6%. The whole mass, therefore, is easily leached; the possible rate of percolation being far in excess of the operating rate, it is obvious that leaching is remarkably uniform and satisfactory.

The system used in leaching is entirely by downward percolation, after, of course, upward submergence of the charge in the first instance; the rate of flow during normal leaching amounts to about 24 in. per hour, measured above the surface of the charge. The flow from each vat is intermittent, a variable amount of soaking being customary, largely because of the need to regulate the flow of solution to the electrolytic department. No circulation of solution in individual vats is practised; it is questionable whether this is a logical procedure in any

leaching operation; any good effects are usually nullified by the fact that the soluble is removed by the solution, only to be again put in contact with the charge; so that whereas the amount of undissolved material in the charge is lessened in amount, the dissolved material in the liquid in the charge, a proportion of which must necessarily be left in contact with the charge as entrained liquor or moisture, is higher in dissolved material than before circulation was commenced.

All treatment solutions used at Chuquicamata consist of spent electrolyte from the tank-house, together with a portion of the wash solution that is moved forward. The acidity is kept constant (about 5.5%) by the addition of sulphuric acid if necessary. During 1920, 2.64 lb. of acid was used per ton of ore treated; at the present time no acid is required. The treatment solution is enriched

TOP OF LEACHING-VAT

in copper by passage through a partly leached charge of ore, after which it comes in contact with fresh ore, remaining thus for a period that varies from 4 to 24 hours. The first effluent, which carries about 46 grammes of copper per litre, then goes to the de-chloridizing and precipitation department. The total time of treatment is about four days, the last day being set aside for water wash and drainage. The amount of water used amounts to about 0.15 ton per ton of ore; the last drain from the vats usually carries about 4 gm. of copper per litre of solution; the amount of moisture in the residue usually averages about 8%. A small proportion of the first effluent (about 15%) is set aside for almost complete precipitation of the copper content, after which it is allowed to run to waste. As with the cyanidation of gold and silver ores, an inevitable fouling of the solution is the result of the continuous re-use of the solvent; from every standpoint it is logical to discharge a small amount at frequent intervals. The water that must be added to displace the copper solution from the charge is in excess of the amount in the residue, an appreciable proportion is lost by evaporation, a small amount by wastage; the remainder must be discharged. The impurities that accumulate in the solution are mostly sulphates of potas-

sium, sodium, and magnesium; nitrates also accumulate and are derived from the salts found in such quantity on the near-by pampa; the nitric acid content of the solution is kept below a maximum by the practice of discharging a proportion of the effluent as barren solution.

In view of the comparative coarseness of the leaching product, the extraction of copper is remarkably high; the results are convincing as demonstrating the fact that large-scale leaching operations are attended with the same or better metallurgic results than small-scale ones. The data from one of the charges that was finished during my stay on the property (on Sept. 21, 1920) were as follows:

Copper in charge	1.71 %
Chlorine	0.06 %
Copper in residue	0.112 %

These figures showed a residue loss of only 6.2% of the copper in the charge; I was told, however, that the result was slightly above the average; the amount of chlorine present was low. On the basis of copper dissolved, as determined by solution assays and tonnages, and the assay of residue, the figures indicated an actual loss of copper in residue of only 6%—thus showing a close agreement with the loss as estimated by the assays of head and tail samples alone. The weight of the charge was 10,998 metric tons, and the total time of treatment was four days. The average loss of copper in residue during 1920 amounted to 7.88% of the copper in the ore treated.

(To be Concluded)

The Gold Premium

At a recent meeting, in London, of the Ivanhoe Gold Corporation, a company operating a mine at Kalgoorlie, in Western Australia, the following remarks were made by Francis A. Govett, the chairman:

"The premium on gold depends on two factors—first, the actual scarcity of the metal itself; and, secondly, the New York exchange, which is just a pressure-gauge indicating the varying balance of indebtedness of Great Britain to America. The scarcity of gold is being exaggerated now by increased demands and by reduced production consequent on the high cost of its production, the main factor in which is the cost of labor. That would seem to point to some possibility that production may continue to decrease, and so increase the premium, and may set off against the company's increased cost. That, however, need not be considered now; still, if only there were in the world a sufficient supply of gold, it would seem that the debtor nations would be sooner able to pay in gold, and the premium would disappear. But so far from there being a sufficient supply, the world's production is now not more than £70,000,000 sterling, against the pre-war output of £93,000,000, and under the present circumstances, as the existing mines grow older and poorer, unless new mines are found to take their place, or unless working costs can largely be reduced, the production is likely still to grow less. At the same time, nations are

now competing for gold, and all the while there is one constant drain, a perfect sink—namely, India. I have seen a computation, which I believe to be correct, that in 21 years to 1919 no less than £253,000,000 of gold has disappeared into hoards in India, which is the result of closing the Indian mints to silver in 1893, since when they have hoarded gold instead of silver—a process that is still going on. There is not the smallest chance of the re-opening of the Mint in India to silver, so as to relieve the gold, which is the course that I would take, and restore the normal monetary standard of the East with its sentimental associations and traditions derived from immemorial usage. One of the two factors, then, is distinctly in favor of the maintenance of the premium, and, therefore, of the continued existence of the Ivanhoe Gold Corporation.

"That being so, we have only to guess at what is likely to be the future of the New York exchange—that is to say, of our probable balance of trade and of our international indebtedness—in order to draw a fair conclusion as to the maintenance of the gold premium. If the proposal I submitted at the Zinc Corporation meeting in 1919 had been carried into effect, that all international war debts should mutually forthwith be cancelled, though it is true it would not have altered the balance of trade it would have enormously altered the international position of indebtedness, which is a vital factor in the exchanges. My own opinion is that the balance of trade will continue to be adverse and that the gold premium will long continue with varying force; therefore the shareholders can console themselves that even if they have to pay a proportion of the increased price for their bread and meat, and everything that they may want and America produces, they can set off still against it some profit from the Ivanhoe mine—as long as the richer stopes hold out—from the gold premium."

BONANZA MINING, states a U. S. Geological Survey bulletin, is a most powerful agency in attracting population, in forming communities, and in establishing transportation systems. Such mining will continue, for the known bonanza deposits in Alaska have been by no means exhausted, and there is a good prospect of finding others. A stable and permanent mining industry cannot, however, be founded on the exploitation of only the very rich orebodies. Permanency must be based on the development of the larger deposits of lesser unit value. Such development depends for its profits not so much on the richness of the ore as on economies made possible by the magnitude of the operations. Large mining operations cannot be successful at places that are served only by the haphazard and expensive means of transportation generally available on the frontier. The passage from bonanza mining to a stable and permanent industry has naturally taken place in all mineral-bearing regions and has long been under way in the accessible coastal regions of Alaska, but the great mineral wealth of the interior remains practically untouched except by the bonanza miner.

Blasting With Liquid Air

*The essential of every blasting agent is the instantaneous combustion and gasification of its two chief components within fractions of a thousandth part of a second, these two chief components being carbon and oxygen combined as indicated by the formula $C + 2O = CO_2$. Formerly the oxygen contained in Chilean saltpetre ($NaNO_3$), was utilized in its combination with nitrogen. Since 1914, however, a new method that allows the use of oxygen in the liquid state has been developed in Germany. The oxygen is combined with a carboniferous agent to form carbonic acid (CO_2). This causes the sudden development of large quantities of gas. Linde was the first to suggest the combination of liquid oxygen with carbon and of utilizing this mixture as an explosive. This was 20 years ago; but it was not until 1914 that the prejudices against this method were finally overcome.

SOAKING- AND TRANSPORTING-VESSELS. The failure of many experiments during the preliminary stages was due to the lack of suitable soaking- and transporting-vessels; but progress was achieved when the Liquid-Air Explosive Co. succeeded in designing a suitable flask. These flasks (Fig. 1) consist of metal spheres with double walls; the surfaces are highly polished where they are in contact with vacuum, radiation being thus prevented. The space between the spheres is evacuated, and contains a carbon substance of special composition. If the flask be now filled with liquid oxygen, the temperature of the carbon substance drops to about -180° . At this temperature the filling develops a considerable degree of absorptive power and acts as a highly efficient air pump, absorbing the last traces of air that may still be contained in the intervening space.

As the volumetric ratio of liquid air as compared with atmospheric air is 1 to 800, the flasks must never be sealed entirely. The warm air of the surrounding atmosphere has little access to the interior of the flask, the neck being made with a small inner diameter, thus rendering the emptying of the flask slow and difficult. This drawback was overcome by the Heylandt patent, according to which the neck of the flask is made as long as possible, so as to allow the inner flask to swing within, and support itself against, the outer one on being tilted (Fig. 2). In this manner metal touches metal at the point of contact, thereby causing an exchange of heat, which results in the liquid in the flask being vaporized. The pressure of the gas in the flask is then utilized for forcing out the liquid air. These flasks are made in various sizes, and possess capacities ranging from 1 to 150 litres. The larger sizes of flasks are used for storing the stocks in hand; the smaller sizes of 3, 5, 10, 15, or 25 litres contents convey the liquid air to the pit. Near the place of employment the liquid air is poured into special soaking-vessels as illustrated in Fig. 3. These soaking-vessels

have capacities varying between 2 and 14 litres; they are cylindrical in shape and also possess double walls, the space between them being evacuated and containing an absorptive carbon substance, as in the case of the flasks. After inserting the cartridges in the vessel, a small quantity of liquid air is first poured into it, in order to create

the vacuum quickly through the action of the carbon substance when cooled down, thus preventing excessive vaporization of the contents. The vessel is then filled so that the cartridges become completely submerged; after a few minutes the cartridges are ready for use. Metal vessels are only used for transporting the liquid air; but

*Abstracted from an article by Bergassessor Lisse in 'Jour. Inst. Ger. Eng.' and re-printed in 'Engineering Progress'.

the employment of special glass has proved satisfactory for the construction of soaking-vessels. Experience has proved that metal vessels are superior to those of glass or porcelain. Moreover, the losses occurring in filling the vessels are far greater with glass and porcelain than in the case of metal.

THE CARTRIDGES. As the cartridges (Fig. 4) are not converted into explosives until after they have been soaked with liquid air, they can be stored or shipped unsoaked; there is no risk of fire or explosion. The cartridges are manufactured with different grades of explosive power by adding substances of higher temperature of combustion, more particularly various hydrocarbons, to the carboniferous substance. Aluminum and magnesium powder are also being used as admixtures.

Substances that are capable of absorbing a large amount of oxygen, as well as of retaining it for some time, are preferably used for the charge, the oxygen evaporating but slowly. Some types of liquid-air cartridges still give excellent blasting results even if 10 to 15 minutes have elapsed since their removal from the soaking-vessel. After the lapse of about half an hour the charge will have lost its explosive power, owing to the complete evaporation of the liquid air.

ELECTRIC PRIMING. Electric priming has proved to be the most reliable method of firing. The 'Vulkan' priming is the one employed with preference by the Liquid Air Blasting Co. It is easily enclosed in a protective casing that prevents the liquid air from affecting the active pill of the primer. If the inflammability of the cartridge has not been reduced by special admixtures, the special primer shown in Fig. 5 is equal to requirements, and produces a long jet flame of high temperature. It consists of a 'Vulkan' primer fitted with a special heading charge. The liquid-air detonator shown in Fig. 6, consists of two parts: the electric priming and the liquid-air detonating cap, stored separately and only fitted together just before being used. The liquid-air detonating cap consists of a small metal tube which is drawn to a point at its forward end. It possesses longitudinal slots, and is filled with a carboniferous substance resembling the contents of the cartridge. The cap is inserted deeply in the cartridge together with the electric priming (Fig. 7). On the cartridge being submerged in liquid air, the oxygen penetrates the cap through the longitudinal slots, and pervades the carboniferous powder contained in the cap. It is impossible to explode either the detonating cap or the cartridge without the presence of oxygen, but the iron cap forms a highly explosive detonator, when charged with liquid air. Fig. 8 shows a liquid-air detonating cap after insertion in the shot-hole.

FIRING BY TAPE-PRIMER. It should be noted that the fuse, if tape-priming is employed, must on no account be covered with gutta-percha or other inflammable material. These substances become brittle through the effect of cold, and may then catch fire at some point where the covering has broken, and from sparks. In such a case the match-cord rapidly burns to the cartridge, combustion

being facilitated by the oxygen present. It is therefore imperative to choose tape having a covering that is impregnated, for instance, with water-glass (potassium silicate), thus ensuring brittleness and unflammability.

In the case of soft shots of a powdery nature, it is possible to fire the blast by means of the jet flame of the tape-primer alone, and without the assistance of a detonating cap, provided that certain precautions are taken and that certain special types of liquid-air cartridges are used for the purpose.

The results obtained in blasting with liquid air are dependent on the choice as well as the method of priming.

ECONOMY OF LIQUID-AIR BLASTING. From an economical point of view this method has proved to be exceedingly satisfactory. After it had been in use for several months in Upper-Silesia in 1915, the cost of the explosive was lower even than in times of peace. The economy of the method is due by a comparatively small consumption of explosive.

SOUTH AFRICAN ASBESTOS. The extensive deposits of asbestos in South Africa have, according to the 'S. A. Mining and Engineering Journal', produced a considerable tonnage of fibre for the past 25 years. Production has been chiefly of blue asbestos or crocidolite from Cape Colony, and chrysotile asbestos from the Transvaal, Natal, and Rhodesia. The 'Cape blue' asbestos is mined chiefly by the Cape Asbestos Co., but lately some other companies have operated in the northern section of the deposit. Such companies, through lack of experience, have turned out a product less carefully graded than that of the Cape Asbestos Co., and have thus tended to lower the standard of blue asbestos. It is claimed that the blue asbestos requires special treatment to prepare it for consumers and, in order to build up a reputation for blue asbestos in the United States, a new corporation associated with the Cape Asbestos Co., and known as Consolidated Asbestos, Ltd., has recently been chartered under the laws of New Jersey. The offices are at 8 West 40th St., New York City, and the works at Bound Brook, N. J. It is the purpose of this corporation to prepare all crude blue fibre for carding machines by a special process. An important feature of the South African industry in the recent production of 'amosite', a ferrous amphibole with or without soda, and somewhat similar to crocidolite, though its color is ash gray to pale brown. A notable characteristic of the material is its fibre length, which reaches a maximum of 11 in. The product from one deposit averages 6 inches in length, and is said to be of good spinning quality. Amosite occurs over an area 60 miles long and 3 miles wide along the Olifants river in the Transvaal. It was discovered in 1907, and commercial production began about 1916. The supply is evidently great and an increasing market for the fibre is to be expected. There has recently been an important development of an amosite property in Seccocoeniland, and output is increasing. The Egnep and Amosa Syndicate mines are in a good condition and large quantities of amosite are said to be available.

Proposed Revision of the Mining Law

The following is the text of a proposed bill prepared by a committee of well-known mining engineers appointed in January 1917 by the Director of the Bureau of Mines, to whom it was recently transmitted.

A Bill to revise, amend, and codify the laws of the United States relating to the location of mining claims on the public domain, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That this Act may be cited by the short title of "United States Mining Act". Wherever the word "person" occurs in this Act it shall be construed to import the plural or singular as the case demands, and shall include individuals, associations, partnerships, and corporations.

Sec. 2. In all cases lands valuable for minerals shall be reserved from sale, except as otherwise expressly directed by law.

Sec. 3. With the exceptions hereinafter noted, all valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, ownership and operation, and the lands in which they are found to occupation and purchase, by citizens of the United States and those who have declared their intention to become such, under regulations prescribed by law. Provided, that this Act shall not affect deposits of potassium, coal, phosphate, sodium, oil, oil shale, or gas; nor shall it pertain to withdrawals of public land which may have been, or may hereafter be, made; nor shall it apply to lands acquired under the Act of March first, nineteen hundred and eleven (Thirty-six Statutes, page nine hundred and sixty-one) known as the "Weeks Law".

Sec. 4. Proof of citizenship, under this Act, may consist, in the case of an individual, of his own affidavit thereof; in the case of an association of persons unincorporated, of the affidavit of their authorized agent, made on his own knowledge or upon information and belief; and in the case of a corporation organized under the laws of the United States, or of any State or Territory thereof, by the filing of a certified copy of its charter or certificate of incorporation.

Form and size of Claim—Requirement as to discovery— Exploration on land classified as nonmineral.

Sec. 5. A. Every full mining claim upon unsurveyed lands shall be located in the form of a square containing forty acres laid out on cardinal lines, conforming to the system of public land surveys, but claims may also be located in the form of a square containing ten acres laid out on cardinal lines, conforming to the system of public land surveys. Other fractional claims shall be located in the same manner as full claims, but their area and form may be governed by available areas. When mining claims are located upon surveyed lands they shall conform to the sub-divisions of the public land surveys. A full mining claim on surveyed lands shall be a quarter-quarter section or lot, but legal sub-divisions of forty acres may be sub-divided into ten acre tracts. Other fractional claims on surveyed lands shall be located in the same manner as full claims but their area and form may be governed by available areas.

B. Subject to limitations contained in this article, discovery of valuable mineral shall not hereafter be necessary in order to locate and hold a mining claim, but when a claim is recorded in the United States Land Office, the records shall include a sworn statement as to whether or not a discovery has been made. A claim located and recorded with-

out discovery on land classified as mineral may be held for five years without discovery, after which it shall be open to relocation under the same conditions as though it were a claim upon which the required expenditure for development had not been made; provided however that upon failure to make discovery within the period of five years a locator shall have the right to hold the claim or claims for further annual terms, not exceeding five years, by payment into the United States Land Office annually in advance fifty dollars for each acre or fraction thereof, which annual payments shall be in lieu of any further requirements for assessment work.

C. Should the owner of a claim located without discovery of valuable mineral make such a discovery during such five-year period, or during such five-year extension thereof, as stipulated in article B of this Section, he shall file a sworn statement as to that fact with the other papers in the United States Land Office, showing the nature of such discovery and of the mineral discovered. Upon the verification of such discovery by a United States deputy mineral surveyor, delegated by the officer in charge of said Land Office to make an examination, which examination shall be at the expense of the claimant, such discovery thus established shall entitle the owner of the claim to hold and possess it under the same conditions as though discovery had been made before the original record was filed in said Land Office. If discovery of a valuable mineral be made by drilling more than one hundred feet in depth, affidavits by at least two persons thoroughly acquainted with the facts, setting forth the nature of the discovery and the place, depth and time at which it was made, shall be accepted by the United States Deputy Mineral Surveyor, delegated by the officer in charge of said Land Office to make examinations, as prima facie evidence of discovery, provided that such affidavits be made within thirty days following the discovery.

D. Where no proceedings have been initiated in the United States Land Office to acquire a nonmineral estate in public land classified as nonmineral, mining claims may be located thereon with or without discovery, but in the absence of a discovery a subsequent location on such land shall not be recognized if made by the original locator, or by any person in privity with him, within two years after the prior location had become invalid.

E. One discovery shall be sufficient to support the holding and patenting of a maximum of four contiguous full-claims, aggregating 160 acres, (if held in common ownership,) or 16 contiguous 10-acre claims, aggregating 160 acres, if held in common ownership.

F. No person shall hereafter locate any mining claim or placer ground in Alaska as attorney for another unless he is duly authorized thereto by a power of attorney in writing, duly acknowledged and recorded in any recorder's office in the judicial division where the location is made. Any person so authorized may locate mining claims on placer ground for not more than two individuals or one association under such power of attorney, but no such agent or attorney shall be authorized or permitted to locate more than two mining claims on placer ground for any one principal or association during any calendar month. No person shall hereafter locate, cause or procure to be located, for himself, in Alaska, more than two such claims, not to exceed 20 acres each in the case of an individual, or 40 acres if an association, in any calendar month; and no such claim in Alaska which is longer than three times its greatest width shall hereafter be patented. Any claim attempted to be located in violation of this article shall be null and void, and the whole area thereof

may be located by any qualified locator as if no such prior attempt had been made.

G. Final entry and payment shall be made for all mining claims located hereafter within seven years from the date of the original location, exclusive of the time consumed in adverse suits and contests; except that in the case of extensions obtained under the provisions of article B of this section the time limit for final entry and payment shall be twelve years from the date of the original location.

H. In all cases of an application for a patent to mineral land a discovery shall be a condition precedent.

Marking, Notice, and Recording of Locations—Annual Development Work

Sec. 6. A. The location of a claim must be distinctly marked on the ground so that its boundaries can be readily traced, and such marking shall include the placing of a permanent monument extending not less than two feet above the ground at each corner of the claim. At the time when the claim is monumented there shall also be posted in a conspicuous place on the claim a notice of location which shall be according to a form prescribed by the United States Surveyor General and in conformity with the terms of this Act. All notices of location of mining claims hereafter made shall contain the name or names of the locators, the date of the location, and such a description of the claim or claims located by reference to some natural object or permanent monument as will identify the claim, and such notice of location of all claims, whether located before or after the effective date of this Act, shall be recorded in the United States Land Office for the district in which located; the claims located after the effective date of this Act shall be recorded within ninety days after the date of location; all claims located prior to the effective date of this Act shall be recorded within one year after said date.

B. On each claim located after the effective date of this Act, and until a patent has been issued therefor, not less than \$5 worth of labor shall be performed or improvements made during each year for each acre or fraction thereof comprised in such claim; or in lieu of the performance of such labor a sum computed at the rate of \$5 for each acre or fraction thereof may be paid each year, including the year of location, into the United States Land Office for the district; on each claim located after the tenth day of May, eighteen hundred and seventy-two and before the effective date of this Act, and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year. On all claims located prior to the tenth day of May, eighteen hundred and seventy-two, ten dollars' worth of labor shall be performed or improvements made during each year for each one hundred feet in length along the vein until a patent has been issued therefor; but where such claims are contiguous, and are held in common, such expenditure may be made upon any one claim.

C. Upon failure to comply with the conditions as to annual work or payments, as provided in article B of this section, the claim or mine upon which failure occurred shall be open to relocation in the same manner as if no location of the same had ever been made, provided that the original locator, or locators, or any person, or persons, in privity with him or them, shall be disqualified for a period of one year from making such relocation and a resumption of work shall not save the original locator, or locators, their heirs, assigns, or legal representatives from the effects of such failure. Provided further; That a sale to an innocent purchaser for value after such failure and after such resumption shall cure such failure in the absence of a relocation prior to such sale.

D. Upon the failure of any one of several co-owners to contribute his proportion of the expenditures required by the terms of article B of this section, the co-owners who have

performed the labor or made the improvements, or who have paid the equivalent thereof to the United States Land Office as is required by article B of this Section, may, at the expiration of the year, give such delinquent co-owners personal notice in writing or notice by publication in the newspaper published nearest the claim for at least once a week for thirteen consecutive weeks, and if at the expiration of ninety days after such notice in writing or by publication such delinquent should fail or refuse to contribute his proportion of the expenditure required by this section his interest in the claim shall become the property of his co-owners who have made the required expenditures.

E. The period during which the annual work is required to be done, as specified in this section, shall be the calendar year during which location of claim be made. Provided, that if it be impossible to finish the work begun during the calendar year of location, and if the work has been diligently and continuously prosecuted, completion of the work, by diligent and continuous prosecution thereof, in the ensuing calendar year shall hold the claim. Provided, however, that this permission may not be construed as a waiver of the performance of the obligatory assessment work during the second calendar year. Provided, further, that on claims located on placer ground in the territory of Alaska said annual work shall be done during the calendar year in which they are located, and regardless of the time of year in which location may have been made.

Extralateral rights and ownership of all minerals and surface embraced within the claim

Sec. 7. Subject to the existing extralateral rights of mining claimants or patentees, the holder or patentee of a mining claim located hereafter shall have the exclusive right of possession and enjoyment of the surface held by him and of the minerals covered by this Act which lie beneath the claim and within vertical planes passing through the surface boundaries of said land, but shall not have the right to follow any mineral deposit beyond said planes. And the holders or patentees of claims heretofore located shall have similar exclusive possession of all the minerals covered by this Act which lie beneath the claim and within vertical planes passing through the surface boundaries of said land that is not covered by any existing extralateral rights.

Proceedings for patent

Sec. 8. A. A patent for any land claimed and located for valuable deposits may be obtained in the following manner: Any person, association, or corporation authorized to locate a claim under this Act, having claimed and located a piece of land for such purposes, and having complied with the terms of this Act, may file in the proper district land office an application for a patent, under oath, showing such compliance, together with proof of a discovery of valuable mineral, together with a plat and field notes of the claim or claims in common, made by or under the direction of the United States surveyor-general, showing accurately the boundaries of the claim or claims, which shall be distinctly marked by monuments on the ground. The claimant shall post a copy of such plat, together with a notice of such application for a patent, in a conspicuous place on the land embraced in such application previous to the filing of the application for a patent, and shall file an affidavit of at least two persons that such notice has been duly posted, and shall file a copy of the notice in such land office.

B. Upon compliance with the terms of article A of this Section the claimant shall be entitled to a patent for the land, in the manner following: The register of the district land office, upon the filing of such application, plat, field notes, notices, and affidavits, shall for the period of sixty days, publish a notice, that such application has been made, in a newspaper to be by him designated as published nearest

to such claim; and he shall also post such notice in his office for the same period. The claimant at the time of filing this application, or at any time thereafter, within the sixty days of publication, shall file with the register a certificate of the United States surveyor-general that twenty dollars' worth of labor has been expended or improvements made upon the claim by himself or grantors for each acre of the claim; or that cash has been paid into the United States Land Office to an amount bringing the total expenditure up to twenty dollars for each acre of the claim; and that the plat is correct, together with such further description by such reference to natural objects or permanent monuments as shall identify the claim; and shall furnish an accurate description to be incorporated in the patent. At the expiration of the sixty days of publication the claimant shall file his affidavit, showing that the plat and notice have been posted in a conspicuous place on the claim during such period of publication. If no adverse claim shall have been filed with the register and the receiver of the proper land office, at the expiration of the sixty days of publication, it shall be assumed that the applicant is entitled to a patent, upon the payment to the proper officer of five dollars per acre, and that no adverse claim exists; and thereafter no objection from third parties to the issuance of a patent shall be heard, except if it be shown that the applicant has failed to comply with the terms of this Act. Provided, however: That in the District of Alaska adverse claims authorized and provided for in this and the following section may be filed at any time during the sixty days' period of publication or within eight months thereafter, and the adverse suits authorized and provided for in the following section may be instituted at any time within sixty days after the filing of said claims in the local land office. Provided, further: That where the claimant for a patent is not a resident of or within the land district wherein the vein, lode, ledge, or deposit sought to be patented is located, the application for patent and the affidavits required to be made in this section by the claimant for such patent may be made by his, her, or its authorized agent, where said agent is conversant with the facts sought to be established by said affidavit.

Adverse claims against applications for patent

Sec. 9. A. Where an adverse claim is filed during the period of publication, it shall be upon oath of the person or persons making the same, and shall show the nature, boundaries, and extent of such adverse claim, and all proceedings, except the publication of notice and making and filing of the affidavit thereof, shall be stayed until the controversy shall have been settled or decided by a court of competent jurisdiction, or the adverse claim has been waived. It shall be the duty of the adverse claimant, within thirty days after filing his claim, to commence proceedings in a court of competent jurisdiction, to determine the question of the right of possession, and prosecute the same with reasonable diligence to final judgment; and a failure so to do shall be a waiver of his adverse claim. After such judgment shall have been rendered, the party entitled to the possession of the claim, or any portion thereof, may, without giving further notice, file a certified copy of the judgment-roll with the register of the land office, together with the certificate of the surveyor-general that the requisite amount of cash or labor has been expended or improvements made thereon, and the description required in other cases, and shall pay to the receiver five dollars per acre for his claim, together with the proper fees, whereupon the whole proceedings and the judgment-roll shall be certified by the register to the Commissioner of the General Land Office, and a patent shall issue thereon for the claim, or such portion thereof as the applicant shall appear, from the decision of the court, rightfully to possess.

B. If it appears from the decision of the court that several

parties are entitled to separate and different portions of the claim, each party may pay for his portion of the claim with the proper fees, and file the certificate and description by the surveyor-general, whereupon the register shall certify the proceedings and judgment-roll to the Commissioner of the General Land Office, as in the preceding case, and patents shall issue to the several parties according to their respective rights.

C. Nothing contained in this section shall be construed to prevent the alienation of a title conveyed by a patent for a mining claim to any person whatever. If, in any action brought pursuant to this section, title to the ground in controversy shall not be established by either party, the jury shall so find, and the judgment shall be entered according to the verdict. In such case costs shall not be allowed to either party, and the claimant shall not proceed in the land office or be entitled to a patent to the ground in controversy until he shall have perfected his title. The adverse claims referred to in this section may be verified by the oath of any duly authorized agent or attorney in fact of the adverse claimant cognizant of the facts stated.

Description of claims

Sec. 10. The description of mining claims upon surveyed lands shall designate the location of the claims with reference to the lines of the public survey. Where such claims are upon surveyed lands and conform to legal subdivisions no further survey or plat shall be required. Where patents have been or shall be issued for claims upon unsurveyed lands, the surveyor-general, in extending the public survey, shall adjust the same to the boundaries of said patented claims so as in no case to interfere with or change the true location of such claims as they are officially established upon the ground. Where patents have been issued for mineral lands, those lands only shall be segregated and shall be deemed to be patented which are bounded by the lines actually marked, defined, and established upon the ground by the monuments of the official survey upon which the patent grant is based, and surveyors-general in executing subsequent patent surveys, whether upon surveyed or unsurveyed lands, shall be governed accordingly. The said monuments shall at all times constitute the highest authority as to what land is patented, and in case of any conflict between the said monuments of such patented claims and the descriptions of said claims in the patents issued therefor the monuments on the ground shall govern, and erroneous or inconsistent description or calls in the patent descriptions shall give way thereto. Where by the segregation of mineral lands in any legal subdivision a quantity of agricultural land less than 40 acres remains, such fractional portion of agricultural land may be entered by any party qualified by law, for homestead or preemption purposes.

Surveys

Sec. 11. The surveyor-general of the United States may appoint in each land district containing mineral lands as many competent deputy surveyors as shall apply for appointment to survey mining claims. The expenses of the survey of mining claims, together with the cost of publication of notices, shall be paid by the applicants, and they shall be at liberty to obtain the same at the most reasonable rates, and they shall also be at liberty to employ any United States deputy surveyor to make the survey. The Commissioner of the General Land Office shall also have power to establish the maximum charges for surveys and publication of notices under this Act; and, in case of excessive charges for publication, he may designate any newspaper published in a land district where mines are situated for the publication of mining notices in such district, and fix the rates to be charged by such paper; and, to the end that the Commissioner may be fully informed on the subject, each applicant shall file

with the register a sworn statement of all charges and fees paid by such applicant for publication and surveys, together with all fees and money paid the register and the receiver of the land office, which statement shall be transmitted, with the other papers in the case, to the Commissioner of the General Land Office.

Verification of Affidavits. Notice of contest.

Sec. 12. All affidavits required to be made under this Act may be verified before any officer authorized to administer oaths. All testimony and proofs may be taken before any officer authorized to administer oaths within the land district where the claims may be situated, and, when duly certified by the officer taking the same, shall have the same force and effect as if taken before the register and receiver of the land office. In cases of contest as to the mineral or agricultural character of land, the testimony and proofs may be taken as herein provided on personal notice of at least ten days to the opposing party; or if such party cannot be found, then by publication of at least once a week for four consecutive weeks in a newspaper, to be designated by the register of the land office as published nearest to the location of such land; and the register shall require proof that such notice has been given.

Land required for mining purposes other than in mineral claims

Sec. 13. A. Where unoccupied land belonging to the public domain, not contiguous to a mining claim, is required by the proprietor of such claim for mining or metallurgical purposes, such non-adjacent land may be located and may be embraced and included in an application for a patent for such claim, and the same may be patented therewith, subject to the same preliminary requirements as to survey and notice as are applicable to mining claims; but no location hereafter made of such non-adjacent land shall exceed 10 acres, and payment for the same must be made at the same rate as fixed by this Act for a mining claim. The 10 acres of non-adjacent land provided for in this section must be in the form of a square, two sides of which must coincide with lines of the public survey. The owner of a mill, or reduction works, now owning a mine in connection therewith, may also receive a patent for his mill site, or works sites as provided in this section.

B. Where unoccupied land belonging to the public domain, either contiguous or noncontiguous to a mining claim, is needful in large areas for mining and metallurgical purposes, the surface rights of such land may be acquired in parcels or lots, conforming to the lines of the public surveys, without limit as to aggregate area, providing the application has been approved by the Secretary of the Interior. Land thus located and acquired under the provisions of this article shall be subject to the same provisions as to survey and notice as are required for the location and purchase of mineral lands in this statute; provided however that no land that has been officially classified by the Federal Government as being capable of irrigation from any known source may be located under the terms of this article. Lands located under this article shall be paid for at the rate of \$10 per acre.

C. The tenure of the surface provided for in article B of this section refers solely to the occupancy of the surface, and the mineral rights underlying land thus acquired shall be in all cases reserved and shall be subject to location and patent under regulations and provisions promulgated by the Secretary of the Interior in harmony with the general provisions of this Act governing the location of mineral lands.

Mineral Development Fund

Sec. 14. All moneys paid into the United States Land Office in lieu of annual labor or improvements and for extension of tenure beyond five years where no discovery has been made, as provided for in this Act are hereby reserved,

set aside, and appropriated, as a special fund in the Treasury, to be known as the "Mineral Development Fund"; to be used and expended, under the direction of the Secretary of the Interior, within the State or Territory, and as nearly as practicable within the mining district, from which payments were made, for general purposes of developing the mineral resources of the several mining districts.

Special Provisions

Sec. 15. Whenever, by priority of possession, rights to the use of water for mining, agricultural, manufacturing, or other purposes, have vested and accrued, and the same are recognized and acknowledged by the local customs, laws, and the decisions of courts, the possessors and owners of such vested rights shall be maintained and protected in the same; and the right of way for the construction of ditches and canals for the purposes herein specified is acknowledged and confirmed; but whenever any person, in the construction of any ditch or canal, injures or damages the possession of any settler on the public domain, the party committing such injury or damage shall be liable to the party injured for such injury or damage.

Sec. 16. All patents granted, or preemption or homesteads allowed, shall be subject to any vested and accrued water rights, or rights to ditches, and reservoirs used in connection with such water rights, as may have been acquired under or recognized by the preceding section.

Sec. 17. The President is authorized to establish additional land districts, and to appoint the necessary officers under existing laws, wherever he may deem the same necessary for the public convenience in executing the provisions of this Act.

Sec. 18. Subject only to such general limitations as may be necessary to exempt navigation from artificial obstructions all land and shoal water between low and mean high tide on the shores, bays, and inlets of Behring Sea, within the jurisdiction of the United States, shall be subject to exploration and mining for gold and other precious metals by citizens of the United States, or persons who have legally declared their intentions to become such, under such reasonable rules and regulations as the miners in organized mining districts may have heretofore made or may hereafter make governing the temporary possession thereof for exploration and mining purposes. Provided: That the rules and regulations established by the miners shall not be in conflict with the mining laws of the United States; and no exclusive permits shall be granted by the Secretary of War authorizing any person or persons, corporation, or company to excavate or mine under any of said waters below low tide; but citizens of the United States or persons who have legally declared their intention to become such shall have the right to dredge and mine for gold or other precious metals in said waters, below low tide, subject to such general rules and regulations as the Secretary of War may prescribe for the preservation of order and the protection of the interests of commerce; such rules and regulations shall not, however, deprive miners on the beach of the right hereby given to dump tailings into or pump from the sea opposite their claims, except where such dumping would actually obstruct navigation; and the reservation of a roadway sixty feet wide, under the tenth section of the Act of May fourteenth, eighteen hundred and ninety-eight, entitled "An act extending the homestead laws and providing for right of way for railroads in the district of Alaska, and for other purposes", shall not apply to mineral lands or town sites.

Sec. 19. No act passed at the first session of the Thirty-eighth Congress, granting lands to States or corporations to aid in the construction of roads or for other purposes, or to extend the time of grants made prior to the thirtieth day of January, eighteen hundred and sixty-five, shall be so con-

strued as to embrace mineral lands, which in all cases are reserved exclusively to the United States, unless otherwise specially provided in the act or acts making the grant.

Sec. 20. No possessory action between persons, in any court of the United States, for the recovery of any mining title, or for damages to any such title, shall be affected by the fact that the paramount title to the land in which such mines lie is in the United States; but each case shall be adjusted by the law of possession.

Sec. 21. The Secretary of the Treasury is hereby authorized and directed to pay, out of the moneys heretofore or hereafter covered into the Treasury from deposits made by individuals to cover cost of work performed and to be performed in the offices of the United States surveyors-general in connection with the survey of mineral lands, any excess in the amount deposited over and above the actual cost of the work performed, including all expenses incident thereto for which the deposits were severally made or the whole of any unused deposit; and such sums, as the several cases may be, shall be deemed to be annually and permanently appropriated for that purpose. Such repayments shall be made to the person or persons who made the several deposits, or to his or their legal representatives, after the completion or abandonment of the work for which the deposits were made, and upon an account certified by the surveyor-general of the district in which the mineral land surveyed, or sought to be surveyed, is situated and approved by the Commissioner of the General Land Office.

Sec. 22. Where by special act of Congress land has been opened to exploration or exploitation under the mineral land laws of the United States but subject to any special limitation or condition expressed in such special act, this Act shall not be construed as waiving such limitation or condition.

Sec. 23. So much of the Act of August fourth, eighteen hundred and ninety-two (27 Statutes at Large, page 348) as provides for the entry of lands chiefly valuable for building stone under the provisions of the law relating to placer mining claims is hereby amended by striking out the word "placer", and hereafter this Act shall be substituted for the placer mining law in the making of such entries.

Sec. 24. The provisions of this Act shall not apply to public lands in the states of Michigan, Wisconsin, Minnesota, Missouri, Kansas or Alabama.

Repealing Section

Sec. 25. The following sections of the Revised Statutes, that is, section 2320, relating to the size of lode claims, section 2322, relating to rights in mining claims; section 2323, relating to tunnel rights; section 2338, relating to rights initiated prior to May tenth, eighteen hundred and seventy-two; section 2329, providing for the location of placer claims; section 2336, relating to placer claims; section 2331, relating to the survey and segregation of mineral lands; section 2332, relating to claims held for a statutory period and to liens on claims; section 2333, relating to the patenting of placer claims; section 2336, relating to intersecting veins; section 2338, relating to State rules for working mines; section 2341, relating to preemption and homestead entries of lands designated as mineral lands; section 2342, relating to the designation of agricultural lands; and section 2344, relating to rights acquired under prior existing law; also the Act of Congress approved June sixth, eighteen hundred and seventy-four (Eighteen Statutes at Large, page sixty-one) relating to expenditures of labor and improvements on mining claims; and the Act of Congress approved February eleven, eighteen hundred and seventy-five, (Eighteen Statutes at Large, page three hundred and fifteen) relating to tunnel work, are hereby repealed; Provided, That nothing contained in this Act, except as expressly provided, shall be construed to affect any right heretofore initiated.

Coalite

At a recent meeting of the Royal Society of Arts, Professor H. E. Armstrong dealt with the use and abuse of coal as fuel, and outlined the early history of coalite. Early in 1913 a large German company was about to associate itself with the English undertaking, but the War intervened, and it was not until 1919 that development work was resumed at Barnsley. A carbonizing plant built to the design of T. M. Davidson had been in operation since November 1920 and was undoubtedly a success. The trouble due to expansion of the fuel on carbonization had been overcome by building the ovens with upright walls and fitting them with perforated hanging plates movable in a vertical plane over a narrow range; the coal was filled into the space between the side of the oven and the opposed face of each plate, thus enabling the width to be varied. During carbonization the plates exerted pressure on the coal, and the volatile matter escaped through the perforations. When carbonization was complete, after 5 to 8 hours, the coalite slabs were allowed to fall into an air-tight water-cooled chamber. It was essential that the coalite should not be exposed to air during cooling. The product contained 10 to 15% of volatile matter and burned with a bright flame; the coal-oil was well within the Admiralty specification for fuel oils; and motor spirit could be obtained from the liquid and scrubbed from the gas.

In the discussion that followed, Sir Arthur Duckham said that the great drawback to the process was the lack of an absolutely satisfactory balance-sheet, and this was the reason why gas-engineers had fought shy of it; the success of the process would depend on the value of the coalite and the value of the oil. Dr. J. A. Harker said that in an investigation carried out under the auspices of the Ministry of Munitions, it was ascertained that from one ton of coal the yield of crude coalite was 14 cwt., of which rather less than 13 cwt. was salable. Economically, the process depended upon selling the 13 cwt. for the same price as that paid for one ton of coal, and of paying operating costs from the sale of by-products. He thought that the margin between profit and loss would be very narrow. Among the points raised by subsequent speakers were the friability of fuel produced by low-temperature carbonization processes and the necessity for briquetting, the economy that should be obtainable with the Neilsen process of internal-heating of the retorts with water-gas, and the need of eliminating as much ash as possible by properly washing the coal. In his reply, the author of the paper stated that the public should be prepared to pay more for coalite than for coal because it did not burn away so rapidly and was smokeless. The yield of fuel oil by carbonization was about 1 ton from 10 tons of coal.

ALCOHOL and dissolved acetylene is a combination that has been adopted as a motor fuel in South Africa. It can be made locally in unlimited quantities and is likely to supersede gasoline.

Company Reports

TENNESSEE COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mines, smelter, and acid plants in Tennessee.

Operating Officials: J. N. Houser, general manager; M. A. Caine, assistant general manager.

Financial: The Tennessee Copper & Chemical Corporation reports an operating profit for the year of \$162,650.53.

Development: Burra Burra mine, 5719 ft.; London mine, 1700 ft.; Polk Co. mine, 230 ft.; total ore-reserves, excluding those in the Eureka mine, 3,533,134 tons.

Production: 507,958 tons was smelted, for a total production of 10,474,881 lb. copper; sulphuric acid produced amounted to 333,629 tons.

BUTTE & SUPERIOR MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill at Butte, Montana.

Operating Officials: C. Bocking, general manager; E. V. Daveler, general superintendent; A. McLeod, mine superintendent.

Financial: Operating revenue, \$3,779,276.43; net income, to surplus account, \$187,928.70. Balance of surplus, \$3,250,049.51.

Development: 16,981 ft., exclusive of diamond-drilling, which amounted to 856 ft.; ore-reserves, 422,100 tons, containing an average of 15.45% zinc, and 5.5 oz. silver.

Production: 334,919 tons was milled, of an average grade of 13.68% zinc and 5.41 oz. silver. The total production of zinc concentrate was 81,836 tons, containing 53.178% zinc, and 19.494 oz. silver per ton.

General: The company has acquired an interest in the Shasta Zinc & Copper Co.; it has also acquired the property of the Bully Hill Mines, Inc., California.

BUNKER HILL & SULLIVAN MINING & CONCENTRATING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill in Coeur d'Alene district; smelter near Kellogg, Idaho.

Operating Officials: Stanly A. Easton, manager; H. M. Sullivan, smelter superintendent.

Financial: Operating profit, \$2,842,106.52; loss, \$561,066.39; dividends, \$1,962,000; dividends to date \$25,193,250.

Production: Ore mined, 409,986 tons; ore concentrated, 523,107 tons; concentrate produced, 96,489.37, containing 36.83% lead and 12.38 oz. silver per ton; net smelter returns, \$4,586,976.26.

General: Operating costs reached maximum during the year. Toward the close, however, more favorable operating conditions obtained, and beginning January 1 a reduction of \$1 per shift was made in the bonus paid to all employees. Operations at the Bunker Hill smelter and refinery were conducted continuously throughout the year with satisfactory results in every respect.

ANACONDA COPPER MINING COMPANY

Report for the year ended December 31, 1920.

Property: Extensive holdings in Montana and in Chile.

Financial: Gross income, \$9,335,253.18; net income, \$2,691,660.62; dividends, \$6,993,750.

Development: 22.55 miles, as compared with 20.39 miles in 1919.

Production: Mine, 2,152,763 tons of ore and 7557 tons of precipitates; copper reduction works treated 2,319,336 tons of ore and other material; the Anaconda works produced

155,339,575 lb. copper, 7,113,659.22 oz. silver, and 32,530,302 oz. gold; the electrolytic copper refinery at Great Falls produced 145,149,892 lb. cathodes; the copper-leaching plant at Anaconda treated 484,352 tons of tailing and 43,271 tons of purchased ore, from which was produced 5037 tons of cement copper; the copper concentrator treated by flotation 181,033 tons of slime from the ponds and 722,769 tons of tailing; the zinc plants treated 443,582 tons of ore and other material; at Great Falls, 101,332,458 lb. of electrolytic zinc was produced and 5,255,452 lb. of zinc in dross and residue, from which were produced 12,536,088 lb. lead, 2,173,080 lb. copper, 2,073,348 oz. silver, and 6151 oz. gold; at the rod-and-wire mill 22,326,478 lb. of copper was manufactured into wire, and 5,292,604 lb. was made into strand.

General: The leaching experiments carried out during the year at Portrerillos, Chile, indicated a consistent extraction of 92% of the copper content of the oxide ores treated. A sulphur di-oxide plant has been shipped to Chile.

RAY CONSOLIDATED COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill in Arizona.

Operating Officials: R. C. Gemmell, assistant managing director; C. A. Smith, superintendent of mines; W. S. Boyd, manager; L. S. Cates, general manager; H. C. Smith, superintendent of mills.

Financial: Net income and proceeds of depletion, \$911,675.24; dividends, \$1,577,179; dividends to date, \$25,412,620.67.

Development: 38,600 ft.; ore-reserves, 83,004,043 tons averaging 2.068% copper.

Production: mine, 1,732,341 tons; ore milled, 1,706,928 tons containing 1.720% copper; concentrate produced, 127,749 tons containing an average of 18.84% copper; net production, after allowing for smelter deductions, 47,062,930 lb. copper.

General: The cost of milling for the year was \$1.24 per ton as compared with \$1.29 for the previous year. The recovery of copper from the sulphides was 90.83%.

UTAH COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at Bingham and Garfield, Utah, respectively.

Operating Officials: R. C. Gemmell, general manager; L. S. Cates, assistant general manager; J. D. Shilling, general superintendent of mines; J. D. Shilling Jr., superintendent of mines; H. C. Goodrich, chief engineer of mines; T. A. Janney, chief metallurgical engineer; D. D. Moffat, consulting engineer of mills; F. G. Janney, general superintendent of mills; R. Hatch, superintendent, Arthur mill; R. H. Hawley, superintendent of leaching plant; E. W. Englemann, consulting research engineer.

Financial: Net operating income, \$3,376,654.19; miscellaneous income, \$1,302,703.71; capital distribution from Nevada Copper Co., \$750,375.

Dividends: \$9,746,940; to date \$111,509,662.50.

Development: No attempt was made to add to the ore-reserves; remaining ore amounts to 364,130,800 tons averaging 1.35% copper.

Production: 5,556,800 tons was milled containing 1.16% copper. Recovery was 81.38%. The net production was 101,897,758 lb. copper, \$542,217.36 in gold, and \$281,116.14 in silver.

General: A suit for alleged infringement of patents was brought by the Minerals Separation Co., in the U. S. District Court for the District of New Jersey during the year. The report states that the answer will be filed in due course; stockholders are advised that the company has a good and meritorious defense.

Book Reviews

The New Stone Age. By Harrison E. Howe. 287 pp., ill. Published by the Century Co., of New York. For sale by 'Mining and Scientific Press'. Price, \$3.

This is one of the 'Century Books of Useful Science', known best through Edwin E. Slosson's admirable volume on 'Creative Chemistry'. The title might suggest a research into the history of primitive man, whereas the subject is the manufacture and use of artificial stone, more particularly cement and its derivatives, plaster and concrete. The ancients used sand-lime mortar; the Romans made a cement by mixing volcanic ash with burned limestone. The secret of this successful mixture, wherewith the Romans constructed their aqueducts, was lost for ten centuries. The modern cement industry started with the Eddystone lighthouse that was built by John Smeaton by aid of a water-resisting mortar that set under water. The previous lighthouses on the Eddystone rock had been wooden structures, although Mr. Howe does not say so. In 1756, the year in which Wolfe at Quebec won this continent for the English-speaking people, Smeaton discovered that an impure clayey limestone gave him a mortar superior to any then in use. He burned the mixture at a low temperature and used only the portion that would slake with water. In 1810 Edgar Dobbs, another Englishman, patented a so-called Roman cement, prepared from lime and clay. This mixture he formed into briquettes, which he burned, to expel the carbon dioxide, but he was careful not to vitrify his product. He, like his predecessors, hesitated to use the portion of his material that had undergone incipient fusion. Yet that was the best of it. In 1824 Joseph Aspdin, of Leeds, England, discovered that if the dust from limestone roads, or ground limestone in general, were mixed with clay, and burned at a higher temperature than any theretofore applied to such mixtures the resulting product after being pulverized yielded a material that hardened when mixed with water, and produced a stone-like substance like the building-stone quarried at Portland, on the coast of Dorset. Hence the name, Portland cement. It was used in the construction of the Thames Tunnel in 1828. The practice of burning the clay-limestone to fusion was then established.

In the United States the use of cement coincided with the building of a number of canals. The first cement produced in this country was derived from a rock near Chittenango, in New York, by an engineer employed on the Erie canal in 1818. The early cement-mills obtained their raw material from various rocks of the magnesian limestone type. Thus the Rosendale cement contained 35.61% calcium oxide, 27.75% silica, 21.18% magnesium oxide, 9.78% iron oxide and alumina. The broken rock was burned in kilns by aid of wood, at first, and coal, later. The clinker from these kilns was ground between burr-stones turned by water-power. The production of natural cement increased steadily in volume until 1899, in which year the output was 9,868,179 barrels. The production of artificial or portland cement has grown from 5,652,266 bbl. in 1899 to 80,287,000 bbl. in 1919. The use of barrels for storing and transporting cement has been discontinued, in favor of sacks, but the old unit of measurement survives. "The process invented by Aspdin is incapable of producing the cement that we know as portland cement", says the author, "for it is not burned at a temperature sufficiently high to produce the one essential ingredient, since discovered by scientific research". That ingredient is tricalcic silicate, in which three molecules of calcium oxide combine with one of silica. "In improving the process [of making cement] by raising the burning temperature to produce incipient fusion, which was accomplished about the year 1825, this constituent was formed, and, while the superiority of the cement so made was early

demonstrated, no one knew why it was better, nor why such burning was necessary to make it better. As in many other industrial processes, the process for manufacturing a superior product was accidentally discovered, but no one gave sufficient thought to why the steps found necessary were taken . . . To the Geophysical Laboratory of the Carnegie Institution of Washington belongs the credit of achieving the first considerable success in learning to what the cementitious character of portland cement is due. . . It would appear [from the experiments conducted by the Carnegie Institution] that the value of portland cement as a cementing material when mixed with water is due to one or more of the compounds—dicalcic silicate, tricalcic silicate, and tricalcic aluminate." Of these, the last one to form is tricalcic silicate, which, as already stated, is the essential constituent of good cement. To the hydration of these compounds is due the 'setting' of cement. The author quotes from George A. Rankin as follows: "When, pure tricalcic aluminate is mixed with water, an amorphous hydrated material is first formed. This material sets and hardens very rapidly. The compound tricalcic silicate, when mixed with water, also sets and hardens rather rapidly. In the case of this compound, as in the case of tricalcic aluminate, the setting and hardening are due to the formation of an amorphous hydrated material on the individual grains, which are thus cemented together . . . From this . . . it will be seen that the setting and hardening involve the formation of an amorphous hydrated material which subsequently partially crystallizes; that the initial set is probably due to the hydration of tricalcic aluminate; that the hardness and cohesive strength at first are due to the cementing action of the amorphous material produced by the hydration of this aluminate and of the tricalcic silicate; and that the gradual increase in strength is due to further hydration of these two compounds together with the hydration of the dicalcic silicate." To produce the maximum proportion of the tricalcic silicate would require a temperature "much too high for economic industrial practice. The best cement-making practice today produces a portland cement containing from 30 to 35% of tricalcic silicate. . . The only conditions under which a larger percentage of lime can be used to convert more of the dicalcic silicate to the tricalcic silicate involves fineness of grinding and temperatures that are uneconomical, working with our present raw material."

Such is the history and the theory of cement-making as told by Mr. Howe. We have quoted enough to indicate the style of his writing, which is colloquial rather than literary. It is a mistake to describe things in terms of the words used for the things themselves, for example, when Swift defined an archdeacon as a person "who performed archidiaconal functions", he explained nothing. So it is a blunder to speak of the "cementitious character of portland cement" and of "the value of portland cement as a cementing material". Such simple and non-technical synonyms as 'binding', 'cohesive', and 'uniting' would serve the purpose better, particularly in a book intended for the general public. The author, at the start, might have told the non-scientific reader that limestone consists mainly of calcium carbonate and that the 'burning' of limestone expels the carbon dioxide, leaving the calcium oxide, or 'lime'. Instead, he uses 'lime' and 'limestone' interchangeably and confusingly. He might have explained that clay is aluminum silicate and that the tricalcic aluminate and silicate in cement come from combinations between the constituents of the clay and the limestone. The author uses 'economic' where he means 'economical'; he is guilty of substituting "preventative" (page 22) for 'preventive'; he employs a singular verb after 'data' ("enough data has been secured", page 43); he makes other lapses from correct literary form, but these will not annoy the average reader, who will give more attention to the matter than the manner of the author's writing, and he will

find the book pleasantly informative. However, it will be caviar to the general public, because it is written in a style likely to attract only those immediately interested in the subject; it is in no sense a book to 'popularize' science, and for that reason it is not in the class with 'Creative Chemistry', but it is worthy of being in a series of "books of useful science" and should be read by every engineer, simply because every engineer uses cement and its derivatives, and ought therefore to understand the nature of these common materials of construction and their methods of use in the arts.

Besides the history of cement and the manufacture of it, the book describes the by-products (notably potash) of the cement industry, the making of concrete, reinforcement, the testing of concrete, the use of cement and concrete in art, in highways, in railroads, in ships, tanks, houses, and in war. The chapter on concrete ships is particularly interesting. For this purpose a cement particularly "strong and plastic" was secured by means of especially fine grinding, namely, so fine that 90% passed a 200-mesh screen. "The aggregates must not exceed half an inch in size; and beginning with sand or gravel or volcanic ash, especially burned clay was ultimately devised . . . One part of cement to one part of specially fused clay below one-quarter of an inch in size, and two parts of this clay between one-quarter and one-half inch in size, gives a concrete with compressive strength of 3380 pounds to the square inch after a seven-day period and 4350 pounds at 28 days. This concrete weighed only 106 pounds to a cubic foot, and made it possible to obtain a ratio of 62% of the dead weight of the total displacement for a 3500-ton ship, as compared with 65.68% for a steel ship and 53% for a wooden vessel. A 3500-ton concrete ship of the standard 150-lb. concrete contains 1761 tons of concrete, 400 tons of reinforcing steel, and 811 tons of wood fixtures, machinery, and equipment. It is seen, therefore, that the total weight of the ship without load is 2970 tons, and that a reduction in the weight of the concrete per cubic foot from 150 to 106 pounds is of decided advantage." This is interesting, but much of it is awkwardly expressed.

The steamship 'Faith', the most notable of the concrete ships launched during the War, has stood the test of service. It was feared that "engine vibration would cause a shattering of the material or the development of large cracks . . . This has not proved to be the case". However, the author is wisely cautious in expressing a final opinion: "Concrete ocean-going ships are new, and we must wait a number of years for performance in actual practice to demonstrate to what extent they are efficient and reliable". It has been found that a small electric direct-current leakage "will cause weakening of the mortar at the cathode, if the action continues an appreciable time, with the result that the bond strength will decrease . . . With alternating current these troubles are avoided". It is inadvisable, says the author, to use brass or bronze castings "adjoining steel reinforcement, since in the presence of an electrolyte there is at once the possibility of local electrolytic action". This, of course, is a technical platitude. The use of concrete in the construction of canal-barges has made considerable progress. "On such waterways they will not be subjected to sagging and hogging, nor to conditions that are responsible for the greatest stresses." Concrete is used for repairing holes in the hulls of vessels until a dry-dock becomes available. Indeed, I may add, travelers to Alaska have been intimidated by rumors that many old vessels so repaired are in use. Obviously the uses of cement are many and various; it is no stretch of imagination to consider this a "new stone age"; we live in an age of stone and metal, and the engineer has proved, in employing them, his traditional ability to utilize the resources of nature to the use and benefit of man.—T. A. R.

Artificial Light. By M. Luckiesh. 366 pp., ill. The Century Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

As the author states in the preface, an endeavor has been made to discuss artificial light in a manner as devoid as possible of intricate detail. The early chapters deal particularly with primitive artificial light; their contents are mainly historical. The science of light-production may be considered to have been born in the latter part of the 18th century; beginning with that period, a few chapters deal with the development of artificial light up to the present time. Until the middle of the 19th century mere light was available, but as time progressed, the light sources, through the application of science, became more powerful and efficient. Gradually mere light grew to more light; in the dawn of the 20th century adequate light became available. In a single century, after the development of artificial light began in earnest, the efficiency of light production increased fifty-fold and the cost diminished correspondingly. The next group of chapters deals with various economic influences of artificial light and with some of the byways in which artificial light is serving mankind. In passing through the spectacular aspects of lighting, the author emerges into the esthetics of light and lighting.

The aim has been to show that artificial light has become intricately interwoven with human activities and that it has had a powerful influence upon the progress of civilization. The book has been prepared with care and is excellently illustrated. It will be read with interest by an appreciative audience.

Tin Resources of the British Empire. By N. M. Penzer. 358 pp., ill. W. Rider & Son, Ltd., 8 Paternoster Row, E.C. 4, London. Price, 15s.

This is the second volume of a series on the subject of the production and resources of the major essentials within the British Empire. The book commences with a brief historical sketch of tin production and a description of the stanniferous ores and minerals. The subject is then considered on the basis of geographical distribution, from which an idea can be formed as to the extent of the deposits within the Empire. An exhaustive study has been made of the deposits in the following districts and countries: Cornwall and Devon, Scotland, and Ireland, in Europe; Malaya, India, Ceylon, Hongkong, in Asia; Nigeria, Gold Coast, Nyasaland, Union of South Africa, Rhodesia, and 'German' South-West Africa, in Africa; Canada in America; and Australia, Tasmania, and New Zealand, in Australasia. The book concludes with an account of the industrial applications, the prices, sales, and the world's output of tin, and a complete bibliography of the subject is appended. It will prove of value as a reliable work of reference.

Gasoline Automobiles. By James A. Moyer. 261 pp., 51 by 8, ill. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

The purpose of this book is to present the essential features of automobile construction and operation, with particular reference to the gasoline-driven machine. There is a growing tendency among owners to keep automobiles for several seasons; deterioration arises primarily from lack of care; much of this deterioration is due to ignorance and the consequent failure to prevent the kind of wear that, if not corrected, will lead to heavy expenses for repairs. The contents of the book are as follows: Automobile Types and Parts; Automobile Engines; Gasoline and Substitutes; Gasoline Carburetors; Automobile Ignition; Magnetos and Ignition Testing; Electric Starters; Clutches, Transmissions, and Differentials; Lubrication and Cooling Systems; Automobile Troubles and Noises; it will be found to contain much material of interest and value to automobile owners.

REVIEW OF MINING

NEW ZINC PLANT IN SHASTA COUNTY, CALIFORNIA, COMMENCES OPERATIONS

The new zinc plant of the Shasta Zinc & Copper Co., at Winthrop, has commenced operation. The smelter has a capacity of 150 tons of ore per day. The net output of zinc oxide will be 30 tons per day. The copper, silver, and gold are saved, too, but they are by-products as compared to the zinc oxide. The zinc is volatilized in the roasters. The copper and silver matte comes from the reverberatory furnace. The zinc is caught in the bag-house as the smoke sifts through 1408 woolen bags. These bags alone cost \$14,000. It was just a year ago that D. C. Jackling and allied capitalists bought the Bully Hill mine and railroad for \$750,000. As much more has been spent since in building the smelter that has just been started. The buildings stand on the site of the Bully Hill smelter that was shut-down in 1909 because zinc in the ore made it impossible to smelt for copper, silver, and gold any longer. Not a semblance of the old works remain. R. L. Beals is general manager; J. H. Rose is superintendent of the smelter; and L. C. Monahan is superintendent of the mines. Seventy-five men will be required to keep the smelter going.

INTERNATIONAL NICKEL COMPANY IS OPERATING AT 20% OF CAPACITY

The report of the International Nickel Co. for the fiscal year ended March 31, 1921, shows a slight decline in earnings as compared with the preceding year. In conjunction with the report the statement of the president, W. A. Bostwick, says in part:

"During the fiscal year covered by this report the business of the company, in common with that of other metal-producing companies, has continued to be much affected by the process of deflation through which the entire world is passing. During the first six months of the present fiscal year a fair volume of business was done, but during the last six months, as the general industrial depression increased and the deflation process progressed, the volume of business was very materially decreased. There were stocks of nickel, as well as secondary or scrap metals still remaining in European markets at the beginning of the year, and these have been only partly liquidated during the year.

"The indications of the last two months in the United States, however, are that stocks in many consumers' hands are gradually becoming exhausted, and the result has been an increased demand, not as yet large in volume, but from an increasingly large number of consumers. During the first half of the fiscal year the company's operations were at approximately 60% capacity. Commencing with the third quarter and, as the volume of business became less, the operations were restricted, until at the conclusion of the year the plants were operated at about 20% capacity, but with sufficient organization retained, and with the plants maintained in such condition as will enable them to increase operations quickly, as the demand for the company's products increases."

The report calls attention to the encouraging market for metal and nickel in special-roll forms, and the provision for greater facilities for production. The company is

constructing a plant on Guyan dock, near Huntington, West Virginia, and expects to be operating and producing here before the close of the year. The regular quarterly dividend of 1½% was paid on the preferred stock out of earnings, but to conserve cash resources, no dividends were declared on the common. The stockholders now number 16,206.

MOVEMENT OF GOLD AND SILVER

Exports of gold from the United States for the month of May totaled \$1,062,521 as compared with \$383,787 in April and \$7,561,683 in May 1920, while imports were \$58,209,918 as against \$82,236,175 in April and \$15,687,859 in May last year. Gold exports for the eleven months ended with May totaled \$132,764,299 compared with \$481,100,731 during the same months last year while imports amounted to \$602,817,925 against \$123,775,217. Silver exports for May totaled \$2,352,609, compared with \$6,862,130 in May 1920 and imports were \$6,956,077 as against \$8,082,895 in May a year ago. Silver exports for the eleven months period aggregated \$51,112,161 as compared with \$174,621,646 in the same period last year while imports were \$55,805,359 as against \$96,337,935 for the eleven months ended May 1920.

PROPOSED DEPARTMENT OF MINES

Senator Nicholson of Colorado made his debut in the Senate by introducing a bill to create a new cabinet position to be the head of the Department of Mines. The bill provides that the proposed new department shall encourage, protect, and promote the welfare of mining and shall cover the coal and petroleum industries, and all metal-mining activities, including iron and all non-metallic mining and quarrying industries, whether of minerals or of 'rock'. It shall, however, not deal with mining products when they pass from the raw into the manufactured state. The Secretary of Mines, as do other Cabinet officers, would receive a salary of \$12,000 per year.

ARIZONA

Patagonia.—E. E. Bethell, owner of the Mollie Gibson mine which adjoins the Mowry, is making good progress in sinking a new shaft.—The mill of the Bland Mining Co., in the Selaro district, is operating steadily.—At the Consolidated Southern Arizona mine the surface plant at the Sweet shaft is being overhauled in preparation for resumption of operations.—Development work on the Hard-shell properties is to be undertaken at once; diamond-drills will be used for the work.

Pearce.—The orebody on the lease of Emmons and Laymon, on the Rainbow claim of the Commonwealth Extension Mining Co. is now said to be three feet wide. The first shipment, which was less than a carload, brought the lessees about \$500 per ton, showing that the ore ran about \$100 per ton more than expected. Interest is manifested as to whether this vein will open out into the big orebody that the late John Pearce always contended lay in the claims known at the Rainbow, Horn Spoon, Arthur, and Silver Thread.

There was a rumor that the Commonwealth Extension Co. had let its rights lapse, but this is a mistake, as the Commonwealth Extension has all its claims patented and has no indebtedness, according to a local man interested in the company.

ARKANSAS

Yellville.—J. G. Ehman and Brant Lahman have leases on the Happy Jack Lead mine, near Onwatta. Ehman says that they have taken out a lot of high-grade carbonate ore and that the prospect is good.

CALIFORNIA

Angels Camp.—The Jolly Tar Mining Co. has received its first carload of machinery, including a hoist and compressor. The mine was formerly known as the Fezzi. It is situated north of Altaville and is on the same belt as the Utica, Angels, and Lightner mines, on what is known as the 'East ledge' of the Mother Lode. The company will start sinking as soon as the machinery has all been installed, and is preparing to go down 500 ft. before doing any drifting or cross-cutting.

Benton.—Work is to be resumed immediately on the claims owned by the Lone Star Co. of Goldfield, Nevada. These claims are opened by a 200-ft. shaft. Assays of \$35 have been obtained from the full width of the south drift on the 125-ft. level and a newly found vein on the surface gives returns of \$80 to \$110 from a 4-ft. vein of gold-silver ore.

Calexico.—Discovery of a rich gold vein in the Cocopah Sierra mountains, 40 miles south of the boundary, was announced on June 9 by two American citizens, who arrived here with nuggets for assay. The men are Alex Cisto and Romaldo Ochoa, residents of Calexico. A general stampede of prospectors for the Cocopah Sierras is expected.

Chico.—The El Oro Gold Dredging Co. has purchased 300 acres of land south-east of here, near Butte creek, and will build at once a dredge which will cost \$100,000. Already an auxiliary dredge is working on the land and two good clean-ups are reported. The dredge now in operation has been leased from the Guggenheim interests, who had been working higher up on Butte creek, but had recently shut-down.

Hayden Hill.—High-grade ore is recorded from the Juniper mines; 65,000 tons of ore is said to be blocked-out on the 100- and 200-ft. levels. A flotation plant erected some months ago is working satisfactorily.

Jackson.—Production has started from the Argonaut mine, the ore coming largely from the caved workings. Unwatering of the flooded workings was completed some weeks ago. The adjoining Kennedy mine is not yet unwatered.

Quincy.—Owners of claims in the Onion Valley district are preparing to start work as soon as supplies can be secured over the Quincy-La Porte road. McFarlane Brothers have resumed work. R. C. Kingdon of the Maxine Mining Co. has arranged for the purchase of a larger pump to handle the water in the mine. Cosker Brothers have found 'pay' gravel in the vicinity of Table Rock. Nave and Bradshaw have begun ground-sluicing near Poor Man's creek.

Redding.—Austin Brothers are preparing to ship barium sulphate from a large deposit, near Copper City, that they leased from the Southern Pacific Co. A spur-track and large bins have been erected to be connected with the mine by an aerial tramway a mile long. The deposit is described as being a "whole mountain".

Sonora.—J. E. King is working the Chileno mine at Jackass Hill. Though 'pockets' are found occasionally in the Chileno vein, the ore is of the milling variety, and in the face of the drift where the rich find was made the shoot of

ore is about eight feet wide. King, Edward Thornton, and W. B. Gohring, of Arizona, have acquired ten claims in the Jackass Hill section, in addition to the Chileno mine.

Sutter Creek.—An important improvement made by the management of the Central Eureka company is the raising of the concrete wall of the tailings dam. The dam is over 1000 ft. long. It has a concrete core with a sand filling above and below. The dam is situated a mile west of the Central Eureka mine. The object in raising the concrete wall is to prevent damage to farm land in the valley.

COLORADO

Alma.—Properties closed down and idle since before the War are resuming and greater activity is reported in the Alma-Sacramento district than for many seasons. The Brownlow, Champaign, Dolly Varden, and Moose mines and Mascotte tunnel are among those where work is being resumed. At the Brownlow a new vertical vein has been opened 24 ft. wide, containing both milling and smelting ore. A new mill has been constructed at the Dolly Varden of 200 tons daily capacity; it will shortly be operating. A sacked shipment recently sent out from the Champaign gave returns of better than \$1000 per ton in gold and silver.

At the Hilltop a large tonnage is broken and shipments will be resumed.

Blackhawk.—The Silver Mountain Mining Co. made another rich shipment to the Pueblo smelter last week; the ore was taken out in sinking the shaft. Settlement netted the company approximately \$2000. The new shoot under development at the 260-ft. level, east, is improving as the drift is extended and assays as high as \$500 per ton are reported.

Colorado Springs.—The Golden Cycle Mining & Reduction Co. paid its stockholders on June 10 a dividend of 2c. per share, totaling \$30,000. The total paid to date is \$9,468,500. The mill is handling practically all ore shipped out of the Cripple Creek district, except for a small tonnage of smelting ore shipped direct to Pueblo.

Cripple Creek.—Increase of \$22,571 in May production over that of April is shown in the report of the mills. The tonnage for May was 43,650 tons with an average value of \$10.53 per ton and gross bullion value of \$450,694. Of this tonnage the Golden Cycle M. & R. Co., at Colorado Springs, treated 21,000 tons of \$14 average grade, total \$294,000; Portland G. M. Co., Independence mill, 20,150 tons, \$5.63 per ton, \$113,444; Lincoln M. & R. Co., Ironclad mill, 1500 tons, \$1.50 per ton, \$2250; and smelters, 1000 tons of \$50 grade, \$50,000.

The Vindicator company has increased its working force by putting on a night shift of between 25 and 30 miners and was preparing to deepen the main or north shaft by raising from the 20th level Golden Cycle shaft to connect with the 19th level Vindicator, a 200-ft. raise, when operations temporarily ceased through the washout on the Midland road, preventing coal from reaching the district. Repairs to the road it is estimated will take until the end of the ensuing week. Other properties may also close due to coal shortage.

Edwards.—The East Lake Milling & Mining Co., and the Packard Power & Mining Co., with offices at Toledo, Ohio, have engaged Nels Nelson as superintendent, and both properties are now being developed. The East Lake company owns approximately 175 acres of patented ground. A water-power plant furnishes power for machine-drills and hoist, and a saw-mill furnishes lumber for mines and buildings. Ore is exposed on both groups and shipments will commence soon.

Georgetown.—Operations have been resumed on numerous properties in districts that draw their supplies from this city. Among these are the Anderson group in Argentine, and the Lead Island group in the same district. The Senator

mine near Dumont is the reported scene of an important find, a 12-in. vein of silver-lead ore has been recently opened and ore is being saved for shipment.

IDAHO

Coeur d'Alene.—The New Caledonia Mining Co. has acquired the Magnet group of seven claims in the Wardner district. Development work will begin soon. The Magnet group adjoins the New Caledonia on the south and east and the acquisition of these claims gives the company 20 claims in the heart of the Wardner district almost surrounded by the Bunker Hill territory. Ore is said to assay 40% lead and 5 oz. of silver per ton. The lower tunnel on the Magnet group is in about 750 ft. and at present the work will consist of running a drift on this level.

An agreement has been signed between the Black Bear Mining Co., the Senator Mining Co., and the Coeur d'Alene syndicate, operating in Burke canyon at Black Bear. The Black Bear and Senator are owners of considerable ground, while the Coeur d'Alene syndicate has a bond on the holdings of the Senator Mining Co., as well as what is known as the Flynn group. All claims lie between the old Frisco and Burke canyon and the Morning mine at Mullan. Provision is made in the agreement whereby work may be jointly arranged, with a pro rata division of cost of upkeep and installation. A large area of exceptionally promising ground will be developed.

Under the joint arrangement between the Bunker Hill & Sullivan and Hecla in the opening of Star ground through the Hecla workings, active surface work has commenced. The 8000-ft. cross-cut will be started. For convenient handling of waste, a skip-pocket, with a capacity of several hundred tons, will be built and from this the waste will be hoisted through the Hecla's main shaft. The cross-cut will be driven on the 2000-ft. level, giving great depth under Star ground. Work on the cross-cut will be pushed as rapidly as possible.

Arrangements have been made to ship ore of the Idaho Continental Mining Co. of Port Hill to the Bunker Hill smelter at Kellogg. Approximately 3000 tons of ore and concentrate is on hand. Steadily the Bunker Hill smelter is reaching out to distant districts for ore. As fast as it obtains reasonable freight-rates the smelting company makes new contracts.—Twenty-five to thirty tons of ore is being hauled from the Sidney mine in the Pine Creek district to the Bunker Hill smelter. The ore contains the highest silver content of any ore ever shipped out of Pine creek, averaging 50 ounces per ton. The property is being worked by W. W. Papesh of Kellogg and associates, who have a lease on the mine.—E. J. Davey, president of the West Hunter Mining Co. in the Coeur d'Alene, has let a contract under which work is to be resumed at once.

The Bunker Hill company is applying 'gunite' as surfacing for the new south mill being erected on the site of the old mill which burned last summer. In addition to affording fire protection, gunite adds to the rigidity and durability of the construction. Gunite is being applied both inside and outside of the storage-bins.

Mackay.—A deposit that is thought to contain uranium minerals has been discovered 50 miles north of here. Before analysis had definitely established the character of the mineral, the entire district was located.—John J. Howell, of the Mount Sullivan Mining Co., states that the last shipment of 35 tons netted the company \$900.

Sandpoint.—J. E. Coleman and D. D. Ward have found an 8-in. vein of silver ore assaying 1500 oz. per ton. The vein was found after driving 32 ft. beyond a fault which cut it off.

Talache.—A concentrating mill on the property of the Armstead mine, on Pend Oreille lake, will be erected this

summer, according to H. H. Armstead, manager and president. Twenty-five men are now employed. The plant will have a capacity of 150 tons daily. The quantity of ore blocked-out is ample to supply the mill. Its average value is \$20 per ton, mainly silver. The quantity is said to be sufficient to retire the cost of the mine, the cost of all development, and the cost of the mill to be built, and leave a profit on all of the money spent. A motor highway from the mine to Sagle, on the Northern Pacific, is being built.

KANSAS

Galena.—The Eagle-Picher Lead Co. has agreed to come into the Galena mining district with such leases as are now signed and start development at once. The first action to be taken is the drainage of the land and the starting of a number of drill-rigs. The grant of acreage to the company

The National Mill at Mullan, Idaho

by several of the land-owners includes some of the pioneer producers of the district. This is considered by mining men as an important development in the movement to induce capital to invest in the Galena district.

MICHIGAN

Houghton.—The Copper Range mines are still experiencing a considerable labor turnover, the most marked in years despite the general depression in the district. During the month of May the net gain at Champion was only 28 men, while the gain for both Baltic and Trimountain was only 12. The men giving up their jobs are going either to the farms or leaving the district. The three mines have only about half of their normal 1915-'16 force. The total, in round numbers, is 1300; of these 600 are employed at Champion, 400 at Baltic, and 300 at Trimountain. While good underground men continue to be taken on at the mines, a reduction in the mill forces has been made possible through increasing the amount of 'rock' stamped per shift. The three mines are shipping a total of 3000 tons of 'rock' daily, of which Champion is furnishing 1900. This is an increase of

100 tons for Champion within the last few weeks. Baltic continues to ship 700 tons daily and Trimountain 400. The yield shows little or no change.

The third cut in wages and salaries, made effective at the Copper Range mines and mills on June 1, brought the total reduction since the depression set in to 32%. The latest cut of 10% makes the wages of the miners \$3.15 per day and trammers and other underground labor \$2.70. Other wages have been reduced in proportion. Little or no complaint was occasioned by the cut, the employees accepting it in the spirit that 'half a loaf is better than none'. Quincy already has in effect a 32% wage and salary reduction, while the total Calumet & Hecla cut is 35%. Wolverine and Mohawk reductions have kept pace with those of Calumet & Hecla, so all the operating mines in the district are now about on the same schedule of wages.

Calumet & Hecla continues to receive timber shipments for underground purposes. The timber is being stored near the mines for use when operations are resumed. It is being delivered by various contractors. The company continues to operate six of its furnaces in the smelting plant at Hubbell.

MISSOURI

Joplin.—In spite of the present dullness there are a number of mines in the Tri-State field making particularly good recoveries just at this time. Among these is the Vinegar Hill Barr mine, situated north of Picher. Across the road to the west is the Commerce Mining & Royalty Co., which is making good production from the north shaft of its Webber mine, where the 'dirt' is reported to be running better than 8%. The U. S. Smelting Co.'s Ritz mine also is a big producer of lead just now, something like 100 tons per week being made. This mine is now being operated by S. H. Davis and W. H. Smith, of Platteville, Wisconsin, and several other associates.

MONTANA

Basin.—It is reported that operations will be resumed at the Jib mine.

Butte.—The East Butte smelter continues to produce at the rate of about 1,000,000 lb. of copper per month. About half of this comes from the Davis-Daly company. The East Butte Co. has resorted to churn-drilling in an effort to determine the thickness of quicksands in a portion of the property through which it is planned to raise to the surface. The new shaft will lessen materially the distance through which it will be necessary to cross-cut before reaching the orebodies.

The Anaconda Copper Mining Co. has contracted with the Pacific Gas & Electric Co., of San Francisco, for the delivery of 10,000,000 lb. of copper wire. This order is said to be the largest ever placed and will be supplied from the Anaconda company's wire-drawing plant at Great Falls. The wire will be used in the construction of a long transmission line from the power company's new hydro-electric power-plant to the distribution system on the Coast.

De Borgia.—The Silver Rock Mining Co. has been financed to the extent of \$100,000 for the development of its property near here. According to J. F. Brown, new machinery will be delivered within 60 days.

Elkhorn.—On the 300-ft. level of the Boston & Montana Development Co.'s mine, the new cross-cut is nearing the Elkhorn vein. Equipping of the 700-ton mill is progressing as rapidly as supplies are delivered.

Elliston.—The Evening Star Development Co. is shipping from the Big Dick mine.

Libby.—W. D. Dilley has started work at the Victor Empire mine. He is backed by Colorado capitalists. The present work consists of extending the main tunnel, which is now 1338 ft. long.

Marysville.—The St. Louis Mining & Milling Co. is preparing to re-open the old Drumlunnon mine that is credited with a production of \$20,000,000 in gold.

Neihart.—It is said that the Silver Dyke property in which there is a large deposit of silver-bearing rock is to be thoroughly developed in anticipation of finding a large body of low-grade ore.

Superior.—It is reported that Gildersleeve Brothers are developing good ore in an adit following a 20-ft. vein. In addition to 9% of nickel, the ore contains gold, silver, and copper.

Troy.—Work is to be resumed by the Consolidated Silver-Lead Mining Co., a consolidation of the Silver Tip, J. P. Lead, and Troy companies. There is a strong vein already prospected by 2400 ft. of adits. It is hoped to find good shoots of lead-silver ore.

NEVADA

Ely.—A statement issued to stockholders by the Copper-mines company says: "Pursuant to notice accompanying our circular letter of April 7, the special stockholders' meeting was held on May 3, and the increase in capitalization was ordered. This makes full provision for conversion of the Consolidated general mortgage bonds and all bonds issued will have conversion privilege at par for the stock and par for the bonds. Considerable sums have been borrowed during the past year to meet necessary expenses and pay interest on bonds now outstanding. It is estimated that to fund this floating indebtedness and carry the properties to July 1, 1922, about \$600,000 will be required. There is every reason to believe that long before that time conditions will have so improved that the larger financing can be put through and construction of the new plant will be well under way."

Eureka.—Eureka-Hamilton Mines Co. reports that the winze in the Pocatillo tunnel has reached a depth of 60 ft., and that the value of the ore averages \$41 per ton. A raise in the same tunnel about 400 ft. from the portal has opened an 8-ft. vein from which assays of from \$35 to \$75 have been secured.

Freiburg.—F. G. Brassell, a Los Angeles broker, has undertaken to finance the Combination Divide for development of 26 claims owned or held under lease and bond at Freiburg, in the north-western corner of Lincoln county, 80 miles from Caliente, the shipping point. The claims were examined recently by Brassell and V. Pistonatti, a mining engineer. They have been opened by several shafts, the deepest of which is 185 ft. The main vein is 12 ft. wide and at a depth of 50 ft. an assay of 12 oz. silver, 15% lead, and 12% copper was obtained from the full width of the vein. There is several hundred tons of ore in the dumps, including 125 sacks of high-grade material. Of the group, 19 of the claims have been worked for 15 years by Charles Briscoe of Pioche, who during this period made many shipments through Caliente. The new owners say they plan to equip the property and build a mill.—The Olympus Mining & Milling Co. has started work on claims formerly owned by the late Judge C. C. Goodwin of Salt Lake City and this company plans to develop the claims and erect a concentrator for the treatment of 2000 tons of \$75 lead-silver ore in dumps. Another company, of which Briscoe is the manager, plans to build a small smelter.

Goldfield.—Simpson, McIntee, and Grim, lessees on the Combination mine of the Consolidated, have shipped a 50-ton carload of \$150 ore, according to samples taken by the Consolidated management. These lessees are now breaking \$20 to \$30 ore and will soon ship a carload of this grade. Other lessees on the Consolidated have five carloads of ore ready for shipment when the Tonopah mills re-open. The Deep Mines shaft is nearing the 550-ft. point. The Kewanas

is drifting north and south on the St. Ives vein in work being done through the Merger shaft. Assays of \$10 to \$17 are being obtained in the north drift.

The Goldfield Development Co. has levied assessment No. 3, at the rate of 1c. per share, payable immediately and delinquent July 9.

Silverhorn.—The adit being driven to get under the high-grade orebody found in the Huson shaft on the Silver Dale mine has entered the vein. The adit has not yet reached the high-grade streak, but assays of \$10 to \$12 per ton are better than was expected in the lean portion of the vein. —In developing the body of milling ore found in his lease on the Silver Dale, George Z. Smith has opened a two-foot streak that averages \$50 per ton. —In prospecting the surface of the Nevada Silver Horn, J. Nelson Nevius found float that shows three different chlorides, argentite, and native silver, and he believes he has found its source. George Smith continues to sack high-grade from the rich streak on his Silver Horn No. 2 lease, and from assays of grab-samples he estimates the average values at this time to be \$200 per ton.

Tonopah.—An important meeting of the hoisting engineers, which it had been hoped would end the Tonopah strike, resulted in the engineers agreeing to remain on strike and it is generally supposed that this will result in the detachment of 50 State police now in Reno being sent here. There have been a number of more or less serious clashes between the strikers and strike-breakers and a number of the oldest employees of the companies, including several bosses, have left Tonopah. After the housing facilities for the strike-breakers had been exhausted, the importation of strike-breakers was stopped for a short time, but this has been resumed. Eastern officials of the Tonopah Mining Co. have given orders to shut-down, but the Belmont and Tonopah Extension are hauling houses from Divide and are building on a substantial scale that indicates they are determined to keep the mines producing. It is expected that the Tonopah Extension mill will be running in a few days. The Belmont is preparing houses for 150 men as the eighth week of the strike draws to a close. The men who have been employed continually by the West End and other companies are giving financial aid to the strikers on the supposition that if the strike is lost their wages will be reduced. However, it is said the West End has no intention of cutting wages.

TEXAS

Austin.—It is reported that samples of salts recently sent from western Texas to the laboratories of the U. S. Geological Survey at Washington contain percentages of potash which suggest at least the richness of the potash deposits of Alsace and Germany. The samples were obtained from two borings about 80 miles apart, sunk by oil companies in the Red Beds region of Texas, where salt beds, red shales, gypsum, and other materials are associated in strata of nearly the same geologic age and general character as the potash-bearing beds of western Europe. The thickness of the potash-bearing beds in Texas represented by these samples is unknown, however, and the questions remain to be determined whether the deposit is thick enough to furnish potash in great amount, or whether it is of scientific interest only.

UTAH

Alta.—After a long winter, during which more snow has fallen than for many years, the mines in this camp are resuming activity. The Little Cottonwood Transportation Co.'s railroad has been cleared of snow, and the equipment overhauled. Shipments of ore have been started from the South Hecla property. G. H. Watson, manager, states that he expects to ship between 6000 and 7000 tons of ore during the summer. The ore-bins, and all available storing areas,

are full of ore which has been mined during the past few months. —The tramway at the Michigan-Utah has been repaired and shipments will be made this summer.

Eureka.—The Apex-Standard Mining Co. has secured control of the Tintic-Zenith and Tintic-Eastern properties, according to Louis Merriman, manager of the Apex Standard. At the same time, announcement was made that the control of the Tintic Union property has passed to the Apex Standard, but it is not certain that the Tintic Union will be merged with the other three properties. The management is pleased with recent development work on the 900-ft. level of the Apex Standard, and it is planned to put on a second shift. Walter Fitch, president of the Chief Consolidated, has acquired a substantial interest in the Apex Standard.

Shipments of ore from this district for the week ending June 4 totaled 119 cars, as compared with 123 cars for the preceding week. The Tintic Standard shipped 44 cars; Chief

Electrolytic Refinery at Hubbell, Michigan

Consolidated, 38; Eagle & Blue Bell, 7; Iron Blossom, 6; Iron King, 6; Dragon, 6; Victoria, 4; Gemini, 2; Alaska, 2; Colorado, 2; Swansea, 2.

During May, the shaft at the Independence Mining Co. was sunk a total of 60 ft., with but one shift on the work. The company is paying \$23 per foot to the contractors engaged on this work, 25% of which is payable in stock of the company.

Park City.—The controversy between the American Smelting & Refining Co. and the Silver King Coalition Mines Co., regarding increase in smelting rates, has been adjusted entirely to the satisfaction of both corporations. W. Mont Ferry, managing director of the Silver King Coalition, states that shipments have been resumed and all probability of any litigation entirely precluded. George W. Lambourne, president and general manager of the Daly-West Mining Co., reports that the differences between his company and the A. S. & R. have not been adjusted. C. W. Whitley, vice-president of the A. S. & R., has been in Utah and had several conferences with officials of both mining companies. It is stated that the smelting contract held by the Silver King Coalition is one of the best smelting contracts, from the producer's standpoint, now in force.

Ore shipments from this district for the week ending June 4 totaled 1097 tons, of which the Judge allied companies shipped 611; Ontario, 268; Silver King Coalition, 218. Shipments the previous week totaled 993 tons.

Salt Lake City.—Announcement was made on June 5 of the reduction from \$22 to \$16.50 per ton in freight-rates on bullion from Utah smelting points to the Atlantic seaboard. The reduction means much to local mining operators. In reality it is a return to the rate effective up to August 26,

1920. On that date, the \$22 rate, which was a 33 $\frac{1}{3}$ % increase, became effective, and local smelting companies immediately deducted approximately one cent per ounce on silver and one-quarter cent per pound on lead contents to cover the additional freight on bullion. It is the opinion of local operators that this charge will now be cancelled by the smelting companies. The announcement of the reduction in freight on bullion, coupled with a price of 5 cents per pound for lead, has created a more cheerful feeling.

The directors of the Utah Copper Co. declared a dividend of 50 cents per share on June 9. This will call for the distribution of \$812,245. On March 31 the company paid a dividend of \$1 per share, and during 1920, distributions were at the rate of \$1.50 per quarter. The grand total of dividend disbursements to date is \$113,946,397.50.

ALBERTA

Peace River.—A discovery of gold is reported to have been made in a creek that empties into the Cadotte river. The Cadotte is a tributary of the Peace river, into which it flows at a point about 35 miles below the town of Peace River. A little excavating and panning seems to have demonstrated the value of the discovery and a large number of claims have been staked.

BRITISH COLUMBIA

Anyox.—The Granby Consolidated Mining, Smelting & Power Co.'s annual report has just been issued, and shows a deficit of \$687,011 for the year 1920. This compares with a deficit of \$984,409 for 1919, but in the latter year dividends amounting to \$1,312,537 were disbursed, while last year no dividends were paid. The company produced 25,081,361 lb. of copper during the year at an average cost of 15.94c., and sold 19,464,796 lb. at an average of 17.85c. The company also produced 9481 oz. of gold and 1,054,206 oz. of silver. The great bulk of the silver was obtained from ore purchased from the Dolly Varden mine, an ore that was utilized for fluxing the company's Hidden Creek ores. The cost of the production of copper has been markedly reduced during the present year, and during the month of March averaged only 12.44c. This reduction has been made possible by a reduction in the wage-scale of the workers, combined with more efficient work.

Nelson.—The directors of the Standard Silver-Lead Mining Co. have announced that, subject to ratification by the shareholders at a general meeting to be held on June 20, the Standard mine has been sold for \$75,000, of which \$25,000 is to be cash, and the balance in two equal installments at one and two years, respectively. Tribute of 20% is to be paid on all ore shipped, the same to apply toward the purchase price. The identity of the purchasers is being withheld. As the directors hold or control the majority of the stock of the company, it is unlikely that the sale will not be ratified. It is understood that the company, which after the completion of the purchase will have more than \$500,000 in the treasury, will continue to search for another mine to develop and work. The Standard has paid more than two and a half millions in dividends.

Stewart.—Despite the advice of the settlement of the strike at the Premier mine that has been circulated throughout British Columbia, the settlement has not been made. Recently the men suggested that the company should meet them half way, and reduce the cut by half. This Dale Pitt, the manager, refused. The men then held a meeting to decide if the proposed cut in the wage-scale should be accepted, and by a vote of 121 to 32 it was decided that it should not.

MEXICO

Coahuila.—Preparations are being made for resuming mining in the old Sierra Mojado district. The Compania

Minera Asarco, through its representative, Walter B. Gates, recently filed upon a group of sixty-seven claims, in that district. They will be developed under the name of El Panama. The fact that the Mexican government is now constructing an extension of the Cuatro Ciénegas branch of the National Railways of Mexico to Sierra Mojado lends additional importance to the district as this road will give a rail transportation outlet to the east.

Monterrey.—Notwithstanding the general unsatisfactory condition of the mining industry, the present year promises to show an output of metals in Mexico that will compare favorably with any previous year, according to Antonio Villarreal, secretary of industry and commerce of the Mexican government. In a recent public statement General Villarreal says there are approximately 20,000 mines now in operation in this country. In a great many cases these properties are producing a nominal quantity of ore, but it is also true that some of the larger mines are working to full capacity. With an improvement in the prices of metals and a betterment of transportation facilities there should be unprecedented activity in Mexican mining.

Pachuca.—Operation of the Santa Gertrudis mill resulted in an estimated loss for the first quarter of 1920 of \$4677. The value of bullion produced was \$53,733, being derived from 32,801 tons of ore from the Santa Gertrudis mine, and 74,948 tons from the El Bordo mines. The price of silver was taken at \$0.559 per fine ounce, as compared with \$0.68 for the preceding quarterly period.

ONTARIO

Cobalt.—The annual report of the Mining Corporation of Canada for 1920 shows that production amounted to 1,644,018 oz. of silver, being an increase of 433,365 oz. over the preceding year. Owing to the decreased price of silver, profits showed a considerable decrease, being \$579,569, as compared with \$908,748 in 1919. An encouraging feature is the increase in the ore-reserves, which were estimated at 2,181,000 oz., as compared with 1,307,220. The Buffalo mine has an estimated ore-reserve of 1,350,060 oz. During the year the Corporation, in view of the ultimate exhaustion of its Cobalt holdings, investigated a large number of properties elsewhere, of which 132 were in Canada and 56 in Ontario. Scott Turner, the company's consulting engineer, states that Canada will continue to be the principal scene of the company's activities.

Porcupine.—The Hollinger Reserve, lying west of the Hollinger Consolidated, has been bought by a syndicate headed by E. A. Osler & Co., of Toronto, stated to include several American financiers. A new company, to be known as the McEnaney Gold Mines, will be formed. The early re-opening of the property is planned. A high-grade vein system has been opened at considerable length on the 300-ft. level.—C. H. Poirier, of New York, has concluded his examination of the Goldale properties, formerly owned by the Bewick-Moreing interests, and is arranging for the commencement of active mining operations.

YUKON

White Horse.—Hundreds of tons of supplies, building material, and mining machinery are accumulating here, for shipment to Mayo. The Yukon Gold Mining Co. and the White Pass Railway are building permanent wharves at Mayo Landing, to accommodate this and subsequent shipments. The Wheaton River district is likely to attract attention this year, and already the Tally Ho mine has been reopened. This district was discovered in 1893, and it contains lodes that carry free gold, telluride of gold, silver, antimonial silver, and silver-lead ores, but little work has been done. It is excellently situated, being only 30 miles from here, and three or four from the White Pass railway.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Wilbur H. Grant is in Mexico.

J. B. Hastings is in San Francisco.

W. A. Clark is here from New York.

S. H. Brady is at the Sheba mine, at Imlay, Nevada.

C. B. Lakeman leaves San Francisco for Alaska on July 1.

Forest Rutherford is in Canada on mine-examination work.

L. R. Budrow, of Douglas, Arizona, was in San Francisco last week.

John McCabe has been appointed assayer at the San Francisco Mint.

W. J. McCormick is now with the U. S. Graphite Co., at Sonora, Mexico.

H. S. Reed Jr. has moved from Shawmut, California, to Millers, Nevada.

Ezra B. Rider, recently at Globe, Arizona, is at Fitch Boy, in Quebec, Canada.

H. C. Hopkins, recently of Tyrone, New Mexico, is at Lead, South Dakota.

L. C. Graton, of Cambridge, Massachusetts, is at Calumet, Michigan, for the summer.

W. W. Wishon is in San Francisco, on his return from Cariboo, British Columbia.

John Tait Milliken has moved from Ingot, California, to Colorado Springs, Colorado.

John Gillie, of the Anaconda company, is expected in Butte on his return from New York.

A. H. Burroughs Jr. has been elected managing director of the Armstead Mines company.

Walter Harvey Weed is examining the Virginia Louise mine at Pioche, Nevada, for the owners.

Ralph Stokes, assistant general manager for the De Beers Consolidated, is in London on a holiday.

W. H. Corbould, manager for the Mount Elliott Copper Co., in Queensland, is expected in London.

Charles F. Sturtevant, of the firm Sturtevant & Bergh, at Salt Lake City, Utah, is at Mayer, Arizona.

Walter Harris, metallurgist to the Old Dominion company, at Globe, Arizona, is now residing at Berkeley.

C. C. Brynton has returned to San Francisco after a visit to the copper districts of Arizona and Montana.

Hugh R. Van Wagenen passed through San Francisco on his return to Copper Mountain, British Columbia.

Walter Fitch Jr., mining contractor of Eureka, Utah, has returned home after a trip to southern California.

A. G. Cadogan, of Berkeley, California, is now with the Potrero Mining Co., at Mocoielo, in Sinaloa, Mexico.

E. J. Franklin, mechanical engineer for the Ray Consolidated Copper Co., at Hayden, is at Salt Lake City.

R. W. French, who returned recently from Chontales, in Nicaragua, is prospecting in Trinity county, California.

Errol MacBoyle has left for Alamo, Baja California, Mexico, to start the re-opening of gold-mining properties.

Joseph Clendenin has been elected a director of the Chile Copper Co., succeeding **William C. Potter**, who has resigned.

W. A. Wilson, mining engineer of Salt Lake City, has been visiting mines in the Wood River district at Ketchum, Idaho.

Henry H. Armstead, president of the Armstead Mines, Inc., is at Talache, Idaho, where he will remain for one month.

Henry M. Adkinson, of Salt Lake City, attended the cele-

bration commemorating the thirtieth anniversary of the founding of the University of Chicago, of which institution he is a graduate.

T. Kawaseki, professor of mining at the Imperial Technical Institute at Port Arthur, South Manchuria, has been visiting mining districts in Utah.

H. O. Graham, chief engineer for the Indiana Public Utilities Commission, has been elected president of the American Association of Engineers.

Cornelius F. Kelley, president of the Anaconda Copper Mining Co., is expected at Butte on his way to his summer retreat on Swan Lake at the end of June.

Frederick Laist, manager of the Anaconda Reduction Works, delivered the Commencement address before the Colorado School of Mines on June 10 and received an honorary degree.

Arthur S. Dwight sailed on June 16 from New York as a representative of the American engineering societies to attend the meeting of the Institution of Civil Engineers on the occasion of the presentation of the John Fritz medal to Sir Robert Hadfield.

Burr McWhirt has resigned as valuation engineer in the Oil and Gas Section of the Income Tax Unit at Washington, to become associated with **J. C. Dick**, who recently opened offices in Salt Lake City and Los Angeles. The firm will specialize in technical questions involving mining, oil, and gas properties, particularly as to matters pertaining to Federal income-tax laws.

Obituary

Frank D. Baker died at Denver on April 29. For a large part of the twenty years during which he was chief engineer of the Colorado department of the American Smelting & Refining Co., he was responsible for, or in close touch with, a great deal of metallurgical plant-construction in the State. Among his inventions may be mentioned a cooler for temperature reduction of calcined materials. He graduated from the University of Illinois in 1888, and was a member of a number of technical societies. He is survived by a widow and five children.

James A. Callahan, for a number of years a dominant figure in northern Idaho, died on June 12 at Wallace. He held much of the stock of the Callahan Zinc-Lead company, in the Coeur d'Alene region, formerly the Consolidated Interstate-Callahan, a property that paid over \$3,000,000 in dividends during one of the years when War melons were being distributed. He recently suffered a heavy financial loss through the forgeries of two Spokane business men; the strain in connection with this case is said to have brought about the illness that led to his death.

P. George Gow was killed in an automobile accident near his ranch at Modesto, California, on June 8. He was born in Scotland 55 years ago. When 18 years old he came to this country, starting in Wyoming. In 1893, he had charge of the exhibit of cyanide at the Columbian Exposition, being at that time connected with the Cassel company, of Glasgow, and taking a prominent part in the introduction of cyanidation in the West through the medium of the Gold & Silver Extraction Co. In 1896 he came to California to manage the Jumpers mine in Tuolumne county. In 1905 and 1906 he acquired a part-ownership in the Dolores mine, in Mexico, by the sale of which he gained a competence for life. For 25 years he lived at Berkeley, where he leaves a widow and three sons. George Gow was well known in Colorado and California as a capable mining engineer and a good man of business. He leaves many friends who grieve his untimely end.

EASTERN METAL MARKET

(By wire from New York)

June 13.—Copper is inactive but easy. Lead is quiet and steady. Zinc is dull and slightly lower.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

ELECTRICITY AND PUBLIC UTILITIES

"From the point of view of industry," says a report by Edward N. Hurley to the Senate Committee on Judiciary, "electrical power has ceased to be a local problem. It has become an interstate problem. Already there are steam and hydroelectric plants built in large units which provide service over a radius of 100 miles or more. It is certain that the larger the generating capacity of an electrical plant, the greater the economy. Small units serving small communities are rapidly becoming obsolescent, and great stations must be built to serve the nation.

"If the proper encouragement is given, the electric light and power industry will spring forward in the next decade faster even than in the past ten years. The result unquestionably will be the lowering of the cost of living and the conservation of national resources with consequent benefit to the whole population. Upon the development and application of electrical energy, more than upon any other thing, are dependent both the speeding up of production and the conservation of our natural resources.

"The almost unlimited water-power of the nation cannot be harnessed for the benefit of the public without enormous capital investment. Officials of public-utility corporations must gain the public's appreciation and confidence if this tremendous project is to be successful. Today there are 1,450,000 American citizens who have put their savings into the securities of the electric light and power industry, and there are millions more who may be listed as indirect investors through the banks and insurance companies. They already have invested five billion dollars, and billions more must be forthcoming if the complete job is to be accomplished.

"The public will invest after it has been taken into confidence by the heads of the electrical industry and made to understand and appreciate the work of utility corporations. It must be realized that confidence in public utility securities cannot be had by constant, unjust criticism, and that the financial standing of a well managed street-railway, gas, or electric-lighting plant is as vital to the life and development of a community as its banks, and therefore should be protected against unfair attacks so that customers and the investing public will have confidence in the properties, resulting in a desire to purchase utility securities when offered.

"In some sections of the country where communities are not receiving proper services of local lighting and transportation companies, the people are advocating municipal ownership. If mismanagement or disregard of the public be proved, then drastic action is warranted, but municipal or government ownership will not give the relief desired."

Hurley admitted having been "at one time sympathetic toward government ownership", but after a number of years in government service he "is convinced that no community can receive the industrial service to which it is entitled under municipal or government management. The cause for this lies in the human element, and the personal efficiency of men in such enterprises is never higher than 50%. From the point of view of 'service to the public,' government operation in industrial service is a flat failure.

"When public utilities realize what high-grade service means and what effect such a service has upon the public, then the question of municipal or government ownership will gradually drop into the background and the public recognition of the difficulties and the need for encouragement and liberality will quickly aid in the solution of this national problem.

MONEY AND EXCHANGE

Foreign quotations on June 14 are as follows:

Sterling, dollars: Cable	3.76 3/4
" Demand	3.77 1/2
Francs, cents: Cable	8.10
" Demand	8.12
Lira, cents: Demand	3.50
Marks, cents	1.52

Eastern Metal Market

New York, June 8.

The markets continue inactive and devoid of features. The price tendency in all of the metals is downward.

Copper demand, particularly foreign, has fallen off, due largely to the fall in exchange.

The tin market has declined for the same reason but buying has been a little more active.

Demand for lead is light and prices have been reduced.

There is no life to the zinc market and values are lower.

IRON AND STEEL

The statistics of both pig-iron and steel ingot production in May bear out the estimate generally accepted in that month that steel works were averaging a 30% operation. In both cases the figures are so close to those for April as to suggest an industry fairly dragging on the bottom, with little in sight pointing to any appreciable change.

In the 31 days of May pig-iron production was 1,221,221 tons, or 39,394 tons per day, against 1,193,041 tons in the 30 days of April, or 39,768 tons per day. For a smaller output in a 31-day month nearly 13 years must be retraced, July 1908 showing 1,218,129 tons.

Thirteen furnaces were blown out in May and seven were blown in—a net loss of six. The 90 furnaces active as June came in had a daily capacity of 38,080 tons per day against 38,505 tons for 96 furnaces on May 1. Current production is at a yearly rate of 14,000,000 tons, whereas output in 1920 was 36,925,987 tons.

The American Iron and Steel Institute's steel statistics, just issued, show that the May output of ingots was 1,503,206 tons, or about 4% more than that of April, with 1,441,537 tons. At the daily rate for May annual production would be 17,980,465 tons. Output in both 1917 and 1918 exceeded 43,000,000 tons.

The volume of current business has if anything fallen off in the week. Definitely lower prices have been established in wire products, and in black and blue annealed sheets. Concessions are made in other finished steel lines, but owing to paucity of the orders price shading is not general.

COPPER

The market has not regained the activity which characterized the early and middle parts of May. There is very little pessimism, however, for it is claimed that the metal is daily going into consumption here and abroad, that stocks are gradually being depleted, and that production is down to a minimum. It is conservatively figured that consumption is 60% of what it was before the War but that production is not over 40,000,000 lb. per month and getting less with most of the mines closed. Because of the fall in exchange in the last week or two, buying for export has declined and there has been no spurt in domestic demand. As a result a few buyers have indicated a willingness to sell at concessions so that electrolytic copper is quiet at 13.25c., delivered, or 13c., New York, for June, with July at 13.50c. and third quarter at 13.75c. Early delivery from most large producers is held firmly at 13.50c.; delivered, with some unwilling to quote earlier than July. Lake copper is quiet and nominal at 13 to 13.25c., delivered.

TIN

The drop in sterling has been the dominant factor in this market the past week. As a result largely of this, values here and in London have dropped appreciably, those here having declined nearly 2c. per pound and those in London from £8 to £12 per ton in the week. Spot Straits tin yesterday was quoted at 29c., New York, while in London spot standard yesterday was reported as £165 15s., future stand-

ard as £167, and spot Straits at £166 15s., with the market weak. Possibly as a result of lower values sales during the week have been fairly large, yesterday about 200 tons changed hands on recessions down to 29c., while on Monday 100 to 150 tons was sold at 29.75c. down to 29.25c., New York. On June 3 there were sales of June-July shipment at 30.50c. with sellers at the close at 30.25c. A feature of the spot market has been its closely held character. Deliveries into consumption in May were 1225 tons with stocks and landing on May 31 at 2571 tons. Imports to June 1 were only 7353 tons, against 23,013 tons to June 1, 1920. Arrivals thus far in June have been 505 tons with 2150 tons reported afloat.

An interesting observation is that one consumer, who ordinarily uses 50 to 75 tons of tin per month, has bought only 20 tons since September.

LEAD

The course of the market has been much the same as the week previous: Characterized by the pressing of speculative lots at St. Louis until on Monday these were offered at 4.60c., St. Louis, or 4.90c., New York. There has been very little buying, however. Probably as a result of this tendency the leading interest on Monday lowered its quotation from 5c., New York and St. Louis, to 4.75c., both locations, for early delivery. The St. Louis quotation of the outside market is consequently a little lower. We quote the market at 4.50c., St. Louis, or 4.75c., New York, for early delivery, with demand light and the tendency easy.

ZINC

There is absolutely no improvement in demand or sales which are still confined to small lots for early delivery. There has been a decline in values, the market falling by its own weight. Prime Western for early delivery is quoted at 4.55c., St. Louis, or 5.05c., New York, with the probability that this could be shaded to 4.50c., St. Louis, or 5c., New York.

ANTIMONY

Wholesale lots for early delivery are quoted a little lower at 5.20c., New York, duty paid. Spot antimony can be obtained at 5.12½c. and has sold at this figure.

ALUMINUM

The market is unchanged with wholesale lots of virgin metal, 98 to 99% pure, quoted by the leading maker at 28c. f.o.b. plant, for early delivery, with metal of the same grade of foreign origin available and sold at 23 to 23.50c., New York.

ORES

Tungsten: Demand is negligible and consumers and dealers are entirely uninterested. Prices therefore are nominal at \$3.25 per unit for Chinese ore and at \$4 per unit for other brands, domestic and Bolivian.

Ferro-tungsten is unchanged at 48 to 58c. per pound of contained tungsten in lump form, guaranteed.

Molybdenum: There is no demand and quotations are unchanged at 50c. per pound of MoS₂ in regular concentrate.

Manganese: High-grade foreign ore is in poor demand at a nominal quotation of 22.50c. per unit, seaboard.

Manganese-Iron Alloys: Demand for both ferro-manganese and spiegeleisen is very light and confined to small lots for early delivery, with quotations nominal at \$75, seaboard, for the British and at \$80 for the American ferro-manganese and at \$30 for spiegeleisen. Production of ferro-manganese and spiegeleisen in May at 9332 tons was the lowest in 20 years and compares with 8360 tons in January 1911, the next lowest figure.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE WAUGHOIST

Engineers of all ages have sought to develop rotary engines because they have realized that they are superior to those of the reciprocating type, and while they have perfected quite a variety of these engines, no entirely successful

by the new 'Waughoist'. While the 'Waughoist' outwardly resembles a number of other hoists in a general way, and is of about the same size and weight as the conventional types now on the market, it contains many vitally important new features by which it is distinguished from all competing

Waughoist—a Portable Rotary Air-Driven Hoist

hoisting-engine of the rotary type had ever been produced until the recent appearance of the 'Waughoist'. In 1858, Ericsson brought out the first compressed-air hoist, which was used in warehouse work in New York. Since Ericsson's time, air-hoist design has progressed by leaps and bounds, but it may be conservatively stated that no such forward step in hoist design has ever been taken as that represented

machines. Chief among these new features is the engine, which is as efficient in performance as it is unique in design.

The 'Waughoist' engine was designed as a rotary engine, first, because it is generally recognized as an elementary fact that machines having a rotary motion have decided advantages over those of the reciprocating type, and, second, because it was found that such a machine would develop a

great deal more power and use less air than the ordinary type.

The accompanying sectional view shows the various parts of the engine in relation to each other. The principal parts are: the motor-housing, the distributor, the cylinder-block, the spider, the spider-shaft, and the pistons.

The whole engine revolves within the motor-housing, an oil- and air-tight casting which protects the engine from the atmosphere and also serves as an oil-reservoir.

The distributor, through which the air is supplied to the cylinders, is a hardened and ground stationary steel shaft which serves not only as a distributor of power, but as a support for the cylinder-block as well. Fixed to the spider-shaft is the spider, a drum-shaped casting, which revolves within the motor-housing and within which the cylinder-block also revolves. Around the inner side of the spider four hardened and ground steel tracks are mounted, on which the piston-rollers run. The spider-hub is mounted on a ball-bearing.

The spider-shaft is a carefully heat-treated alloy-steel shaft upon which the cable-drum revolves. A clutch-pinion is mounted on the small end of the spider-shaft so that the cable-drum gearing can be disconnected from the engine and the drum permitted to run free when desired.

Within the four cylinders are four carefully heat-treated, precisely-ground, drop-forged, alloy-steel pistons, which, as the cylinder-block revolves, work in the cylinders and at the same time roll the piston rollers along the track-plates on the inner side of the spider, thus practically eliminating the sliding surface friction common to all other types of engines.

Not long ago a sectionalized model of the 'Waugholst' was shown for the first time at a meeting of the American Mining Congress, where it proved to be the sensation of the exhibition. Engineers from all sections manifested the keenest interest in the construction of the machine and were frankly mystified by its amazing efficiency. Almost without exception, after a demonstration, the question was asked on every side, "What makes it go?"

By referring to the sectional view, the idea of the operation of the machine will be readily grasped. Throughout the description it should be kept in mind that the cylinder-block is set in the spider, eccentric to the spider-shaft, by means of which the cable-drum revolves. Compressed air is admitted to the machine through an opening (not shown in the sectional view) against the control-valve.

When the control-valve throttle is thrown open, the air rushes through the narrow portion of the valve into the air ports on one side of the distributor, passing through it to the distributor-slot on the corresponding side. At this point the distributor is divided by a partition into two chambers. Reaching the distributor-slot, the air is admitted through the cylinder-ports into the cylinders which happen to be in contact with that side of the distributor-slot. Recall here that the cylinder-block is set in the spider off centre, but that the spider is mounted on the spider-shaft at its centre. Now, as the air is admitted into the cylinders on one side of the distributor-slot, it pushes against the pistons, which are held to the roller-tracks by flanged-steel plates and this push, aided by the off-centre movement of the cylinders on the roller tracks, revolves the cylinder-block and the spider with it.

While the air is being admitted on one side of the distributor, it is being exhausted through the piston-ports on the other, and to reverse the machine instantly it is only necessary to push the control-lever in the opposite direction, which reverses the function of the air-ports so that the side in which it has a moment before been admitted becomes the exhaust side and vice versa.

One of the most noticeable faults of the ordinary hoist is the excessive vibration set up when the machine is in operation.

In the 'Waugholst', vibration is negligible at all speeds and loads. Unlike any other portable hoist, it vibrates so little that it can be run free at high speed without being fixed to any foundation, and its purring motor runs as smoothly and easily as that of the finest automobile engine.

While the 'Waugholst', coming fresh from the factory, is thoroughly efficient, and possesses a horse-power that is surprising in so small a machine, its potential horse-power is much greater, and a gradual, continual, and substantial improvement may be counted upon for a considerable length of time after installation. In this respect the 'Waugholst' resembles an automobile engine, which is invariably more efficient and powerful after having been 'run in'.

In proportion to its size and weight, the speed and load possibilities of the 'Waugholst' are greater than those of any other portable air-hoist. The descent of a heavy load may be speeded up by a full head of high-pressure air and, by shifting the control-lever, the engine can be instantly reversed from full speed ahead without the least injury to the mechanism.

HERCULES POWDER CO. ABSORBS AETNA COMPANY

Rumors of the proposed purchase of the Aetna Explosives Co., Inc., by the Hercules Powder Co. received definite confirmation on June 6 when the Aetna stockholders sanctioned the sale of its properties, assets, and business. This marks the culmination of a transaction that has interested financial and business circles for the past two years, and which in addition to being a deal of considerable moment also presents an unusual legal aspect.

Although it has been understood practically since the close of the War that negotiations were under way between these two manufacturers, it was not until the petition of the Hercules company for permission to purchase the Aetna company had been acted on favorably by the Circuit Court of Appeals, sitting as the United States Court for the District of Delaware, that the proposition assumed definiteness. The Hercules company was originally created by a decree of a Federal court in an action brought by the United States against the du Pont company under the Sherman Act. Although not a party to this action, the Hercules company is bound by certain injunctions in the final decree, and for this reason it was deemed necessary to petition the court for permission to effect the present transaction. On May 4, a decision was rendered on the Hercules company's petition, sanctioning the purchase of the Aetna company, in which the court expressed itself as convinced that in permitting the Hercules Powder Co. to buy the Aetna company, actual competition would be undiminished and even probably increased, especially as regards the Hercules company's strongest rival, the du Pont company. The case was heard before Judges Buffington, Woolley, and Davis.

Judge Woolley, who wrote the opinion, also pointed out that events have justified the theory of the dissolution decree that the stock control of the Hercules Powder Co. would in time pass out of the hands of those interested in the du Pont company. In this he referred to evidence presented that whereas at the time of its organization less than 1% of the Hercules company's common stock was owned by its directors and employees, on September 15, 1920, this same group held 37.04% of the voting common stock and represented the largest single group interest in the company. This stock, taken together with that which is owned by those having no connections with either company which would vote with the existing management, judged by the usual experience at corporate elections, amounts to control by a substantial majority.

By this purchase the Hercules company will acquire high explosives, or dynamite, plants near Birmingham, Alabama; Emporium, Pennsylvania; Sinnamahoning, Pennsylvania; Ishpeming, Michigan; and Fayville, Illinois; two black-

powder plants, one at Goes Station, Ohio, and the other near Birmingham, Alabama; a plant for the manufacture of blasting-caps and electric blasting-caps at Port Ewen, New York; and a plant for the manufacture of fulminate of mercury, for use in blasting-caps, at Prescott, Ontario, Canada.

The explosives industry differs from most others in that it is limited geographically in making sales because of freight-rates. It is only possible to ship such commodities a limited distance from the place of manufacture before a point is reached at which transportation costs make it impossible to compete with other companies having plants nearer the particular consuming centre. The principal significance of this transaction to the Hercules company is that it will in the future, because of the situation of the Aetna plants, be able to enter territories in which it has previously found it unprofitable to sell. It will thereby compete all the more successfully with other explosives manufacturers.

In the unanimous decision of the court on the petition referred to above, Judge Woolley states in part:

"A careful review of the explosives industry set forth by the petitioner in elaborate detail with reference to areas of consumption, number and distribution of producing plants, and competitive conditions, the accuracy of which is in no particular challenged, has convinced us that in permitting the Hercules Powder Co. to acquire the several properties of the Aetna Explosives Co. actual competition in the industry within their respective regions will remain undiminished, though the number of competitors will, of course, be reduced by the withdrawal of one. Indeed, it is persuasively represented that competition will be increased by thus strengthening the Hercules Powder Co. in its contest for business against the du Pont company, its strongest rival. However that may be, we are satisfied, after a careful study of a great volume of data gathered from authentic sources, a recital of which in this opinion is quite impracticable, that the proposed purchase of the Aetna properties by the Hercules Powder Co. will not disturb the position in the industry which the court has made for the Hercules Powder Co.; that it will not abridge the purpose for which the court employs that company in maintaining the separation of the offending members of the combination previously existing; and that it will not throw out of balance the competitive conditions in the industry which the court sought and which evidently it has achieved by the instrumentalities of the Hercules Powder Co."

"With the Aetna company's business, the Hercules Powder Co. becomes a much larger factor in the explosives business of the United States," said J. T. Skelly, vice-president of the Hercules company.

"The company is now in a position to compete for business in all parts of the United States, and will be greatly strengthened in important fields which have hitherto been closed to us on account of freight-rates from our plants.

"The reorganization will take place gradually. As in some cases we already have branch offices in cities where there is an Aetna office, consolidations will be necessary and new alignments of branch-office territories must be worked out. It is our intention to retain as many members of the present Aetna organization as we consistently can, but obviously, one of the great advantages of this purchase will be the reduction in overhead which it will make possible. Ultimately the principal members of Aetna's home office organization will be transferred to Wilmington."

NEW STOPING RECORD ON THE RAND

At the Geduld Proprietary Mines, on the Rand, L. H. Ellitson recently established what is claimed to be a new world's stoping record when in one month he broke 215 fathoms of rock, the previous world's record having been 190 fathoms. Three No. 18 Ingersoll-Leyner drills were

used, the fathoms per machine-shift being 2.56, and 40 tons being broken per machine-shift. The stoping width was 63 in. In the three months preceding the same miner broke 185, 185½, and 190 fathoms, respectively, with the same machine. According to the Union Corporation, Ltd., which operates the Geduld mine in which the record was made, the Leyner stoping in this mine averaged 1.7 fathoms per machine-shift for 1920 for 88 machines running.

COMMERCIAL PARAGRAPHS

The new P & H shovel-attachment for use with standard P & H types 205 and 206 excavator-cranes is described in Pamphlet SX just published by the Pawling & Harnischfeger Co., of Milwaukee. Illustrations of the shovel attachment in use are shown and the economy of being able to use either the 30-ft. crane-boom or the shovel-boom is pointed out. With the extra expense of only the shovel attachment, the number of applications of this material-handling and digging machine is increased—the shovel, it is said, having the ability to do the work of any steam-shovel of equal weight.

Lunkenheimer 'valve-iron', as found in 'Ferrenewo' valve-bodies, is especially alloyed and processed to provide, in addition to its high tensile strength of 30,000 lb., those peculiar qualities essential to successful results under the wide range of service conditions for which the 'Ferrenewo' valves are adaptable. It should not be confounded with even the better trade-grades of cast-iron. Prior to the development of the 'Ferrenewo' valves the use of small-size globe-, angle-, cross-, and check-valves with ferrous bodies was, for wise and sufficient reasons, not considered as being good engineering practice; and the 'Ferrenewo' was not released to the market until the full merit of its body material had been soundly established. The application of the Lunkenheimer 're-grinding' principle to the construction of 'Ferrenewo' valves has made an ideal product.

A new bulletin recently issued by the New Jersey Meter Co., of Plainfield, New Jersey, describes a forge-blower recently placed on the market. This blower is applicable for coal- and coke-forges used in heating steel for dressing or tempering, supplying air for gas- and oil-furnaces, and for rivet-heating forges. This device turns a small volume of compressed air into a large volume of low-pressure air. To illustrate, a small rivet-heating forge requires an average of 45 ft. of free air per minute to blow the fire. If taken direct from the compressed-air lines, this represents an expenditure of 7.5 hp. With the blower attached, the consumption of air from the lines is less than 2 ft. per minute (representing only ¼ hp.) and the balance or 43 ft. per minute is induced or drawn in from the atmosphere. This is 'free air' with a new and profitable meaning. Seven horse-power saved, on a single forge, may amount in the course of a year to \$300 or more.

In 1902 the Sprague Electric Works developed a small electric hoist to be used in places where it would be difficult or impossible to install electric cranes. Several hundred were manufactured and quickly sold and the users found that they possessed many advantages over chain-blocks, air-hoists, and large electric cranes. Many of these first machines that were built over eighteen years ago, are still in use, and have been giving continuous service since they were installed. To meet the various hoisting requirements of the many industries, several types with various capacities have been developed and many improvements have been made to the original designs. Sprague electric hoists are built in capacities of from one-quarter of a ton to six tons and in two general types, worm-gear hoists and spur-gear hoists, and for both direct current and polyphase alternating currents. Bulletin No. 48,967 recently issued describes a large number of these machines and illustrates uses for which they are particularly applicable.

REVIEW OF MINING

MEETING OF THE ARIZONA CHAPTER OF THE AMERICAN MINING CONGRESS

The Arizona chapter of the American Mining Congress met at Bisbee on June 13 and 14. The program for June 13 included the following: 'Present Conditions of the Copper Industry in Arizona and the Way Out', John C. Greenway; 'Steam-Shovel Operations on Sacramento Hill', Gerald Sherman; 'Powder', D. T. Fogg; 'Employees Representation', G. H. Dowell.

Mr. Greenway said: "There is a great field for the copper

and said that in his opinion, if a rate of \$6.50 could be secured from here to San Pedro a saving could be effected by shipping to Brooklyn by water.

SAN FRANCISCO SECTION OF THE AMERICAN INSTITUTE OF MINING ENGINEERS TO MEET AT VIRGINIA CITY

A field meeting of the San Francisco section of the A. I. M. & M. E. will be held at Virginia City, Nevada, June 27 and 28. Members going by train should leave San Francisco

The Gold Canyon Dredge Near Virginia City, Nevada

industry in Arizona by securing an outlet on the Gulf of California. This can be accomplished by the extension of 102 miles of track to a point that can be made suitable for the purpose by the construction of a breakwater and pier. This would be an extension of the little road from Gila Bend to Ajo, and from there to the gulf. The route is easy and the construction would be comparatively inexpensive."

He said that an estimate, based on existing rail-rates, indicated that if all the copper companies in Arizona shipped their product by the proposed route they would save a total of \$6,000,000 annually.

"The freight situation with regard to bullion", said Mr. Greenway, "is this: In 1907 the rate from Douglas to Brooklyn was \$8.55, and the present rate is \$20. The railroads expect to make a reduction to \$16.50, and say that they cannot reduce further. I accept the fact that they cannot reduce further, and believe this road would be a great thing for the copper producers of Arizona."

He spoke of the comparatively cheap shipping rates on the Pacific Coast, and by water from the coast to Brooklyn,

at 7 o'clock Sunday evening, train No. 6, arriving at Reno at 8:10 the following morning. Automobile transportation from Reno to Gold Hill will be provided for those members giving notice of their desire to so. Members will meet at the Jacket mine-office, at Gold Hill, at 10 a.m., June 27, and visit the mines and works of the United Comstock Mines Co. The afternoon will be devoted to a visit to the dredge of the Gold Canyon Dredging Co. The business meeting will be held Monday evening, when papers will be read by George J. Young on 'Mine Development at Gold Hill', and Gerald H. Hutten on 'Dredge Mining Practice'. On June 28, members will meet at 10 a.m. at the office of the Con. Virginia Mining Co. and pay a visit to the North End mines.

Mining is thriving in the Comstock region and the visit should be a profitable one. The United Comstock Mines Co., an enterprise directed by Bulkeley Wells and associates, embraces eleven old properties. It is probably the largest low-grade silver project in the world, and the preliminary arrangements before a pound of ore is run through the mill will cost \$2,500,000. The company has acquired control of

the Alpha Consolidated, the Consolidated Imperial, the Confidence, the Challenge Consolidated, the Yellow Jacket, the Crown Point, the Belcher, the Kentuck, the Seg. Belcher, the Knickerbocker, and the Globe Consolidated. The central features of the project are a 10,000-ft. haulage tunnel linking up all the properties, and a mill on Gold Hill which will have a capacity of 1000 tons per day. At the Imperial the shaft has been sunk to the 400-ft. level, with drifting and cross-cutting until 2,200,000 tons of ore has been blocked-out.

The properties acquired by the corporation extend for 10,000 ft. along the Comstock Lode. Ore has been demonstrated for a width of 75 to 100 ft. and for more than 5000 ft. along the Lode. The two-mile haulage tunnel is being driven from seven faces and is now about one-third completed. The ore is to be worked by the branch-raise system, which has been perfected in large porphyry copper properties in Nevada and elsewhere.

The Gold Canyon Dredging Co., of which Wells is president, has completed the construction of a dredge that represents an investment of \$350,000.

The machine is constructed wholly of steel and weighs 900 tons. It is 108 ft. long and 52 ft. wide and has 2500-lb. buckets which can be loaded and dumped at the rate of

20 per minute. There is enough gold-bearing ground in the vicinity to keep the dredge running 24 hours per day for five years. Twenty men are required to operate it.

THE ZINC INDUSTRY

The whole Joplin district has been shut-down. The country today is getting almost all its domestic zinc from the Tri-State district—embracing Kansas, Missouri, and Oklahoma. But even there, only 30 mills out of a total of 200 in the field are operating, or about 15% of capacity. This district, too, is able to operate only because of the rich quality of the ore. In April total output of zinc in this country amounted to 17,000 tons, or about 1500 tons below consumption, reducing surplus stocks in corresponding degree. Zinc stocks today are estimated at between 80,000 and 83,000 tons. But these stocks are not causing worry. The steel business is flat; galvanizers are therefore not buying any metal, and in normal times galvanizers take 66⅓% of the zinc output of the country. The American Zinc, Lead & Smelting Co. operated at a slight profit in April, the first time in many months. Final figures for May are also expected to show a balance on the right side of the ledger. The company is operating at not more than 30% of capacity

Reasons for Marcy Roller Mill Success

The large capacity and high mechanical efficiency of the Marcy Roller Mill is due to:

(1) The Marcy low pulp-line feature which permits grinding in very thick pulp, thus coating thoroughly rods and liners with pulp to be ground. In this manner the rod-load produces maximum grinding results.

(2) Rods working on thin layers of thick pulp and the non-cushioning and non-buoyant effect of the pulp on the rod-load due to the low pulp line.

(3) The Marcy open-end feature permitting quick and easy inspection of the interior of the mill, providing an easy means for putting in and taking out rods and liners, thus keeping the grinding medium up to the highest efficiency.

(4) The use of cheap wearing parts and the low power consumption per ton of ore ground.

The Marcy Roller Mill is the only grinder of this type whose design embodies all of the above principles and this accounts for its instant success and its great efficiency.

T. A. RICKARD, Editor

WHAT trouble the Irish question can make is shown by the proceedings of the American Federation of Labor assembled in convention at Denver. It is a non-American question and it is deeply regretted that it should serve as a cause of discord among our own people, whether admirals or laborers.

SSILVERHORN is a mining camp where there is a revival of activity in a part of Nevada heretofore best known through the fame of Pioche, where also, we are informed, there are signs of awakening. Within three months the census of Silverhorn grew from nothing to 300, and it promises to be able to boast 1000 inhabitants by the middle of summer. We thank Mr. T. H. M. Crampton for sending us the timely information in his article, which will be found on another page of this issue.

THE Senate resolution suspending assessment work on mining locations beyond July 1 has received an adverse vote in the committee of the House. This means that the assessment work for 1920 must be started before midnight of June 30 and pursued continuously until completed to prevent re-locations by other parties. The work for 1921, unless excused by further legislation, must be done before December 31 of this year. This is in accord with public opinion, especially among prospectors, as our columns have shown.

CONTRARY to sundry published reports, we learn from an authoritative source that the 10 million pounds of copper recently sold to the Pacific Gas & Electric Company netted the Anaconda Copper company 14 cents per pound for ingot metal. In other words, after the actual cost of passing the copper through the rod-mill and drawing it into wire, amounting to between 3 and 4 cents, has been subtracted from the selling-price, 14 cents remains. The particular metal that will be used to fill the order has been in the company's warehouse at Great Falls for many months; doubtless the mining, smelting, and refining cost fully 14 cents per pound. On the other hand, under the conditions existing at the present time, the Anaconda company could probably make a substantial profit by selling at 14 cents. Incidentally, it would be cheaper to send the wire to Seattle and ship it to San Francisco by boat than to transport it by rail for the entire distance; however, the new freight-rates

that were recently announced will equalize the cost, and the railroads will accordingly get the business. Delivery is to be made before September 1.

POLITICS is a dirty business most of the time, and when it becomes injected into an educational system it makes no end of trouble, as has been seen in the recent history of the Colorado School of Mines, whose reputation has been saved, not by anything done by its trustees or by the Legislature, but by the excellent records made by its graduates. We say this in order to give emphasis to our pleasure in announcing the acceptance by Mr. Stanly A. Easton of an appointment as a member of the State Board of Education and Board of Regents of the University of Idaho. The Dean of the School of Mines, Mr. Francis A. Thomson, writes to us to express his delight with the appointment, and we can well understand his feelings on the subject. The manager of the Bunker Hill is exactly the broad-minded clear-headed man to be a sagacious trustee for an educational establishment; himself a graduate from the University of California and a remarkably successful mining engineer, he has shown a wise humanity in his management of men and a keen response to everything that is progressive, not only in technical matters but in social institutions. The Governor of Idaho has set a good example to the executives of neighboring States.

ADDITION of another member to the President's Cabinet, to be known as the Secretary of Mines, is proposed in Senate bill 1957, introduced by Mr. Samuel D. Nicholson, the new Senator from Colorado. The function of the proposed department is "to encourage, protect, and promote the welfare of the mining and mineral industries", including "the coal, petroleum, and gas industries, all the metal mining industries, including iron and all the non-metallic mining and quarrying industries whether of minerals or rocks". The Department, however, is not to "deal with metals or mineral products, nor with any problems pertaining thereto when they pass from the raw into the manufactured state". It is proposed to abolish the existing Bureau of Mines and the Geological Survey, and to create a Bureau of Mining Technology, a Bureau of Mining and Applied Geology, a Bureau of Mineral Markets, and a Bureau of Public Mineral Domain, together with sundry lesser "divisions". While we can see probable advantages to the

mining industry in the creation of a separate department and can recognize some merit in the proposed plan of organization, we do not believe that the measure is wise, for at least two reasons: first, the Cabinet is large enough as it is; and, second, the country is hoping, with varying degrees of confidence, that a complete reorganization of the executive branch of the Government will be effected shortly. The accomplishment of Senator Nicholson's plan would merely complicate the already perplexing task of re-arrangement; it should be made a part of the more comprehensive plan for reorganizing the entire administration at Washington.

JUDGE GARY'S comments at the recent meeting of the American Iron and Steel Institute shed a new light on the present economic situation. "There is nothing the matter with the country," he said, "it is with the individuals." Profiteering is being carried on alike by the seller and by the consumer. The seller's turnover is smaller than normal, so he maintains a high level of prices; the consumer postpones his purchasing and restricts his spending. In other words, says the chief spokesman for the U. S. Steel Corporation, the consumer tries to profiteer by not buying until there is a complete and, to him, satisfactory readjustment of price-levels; he is conducting a passive-resistance strike. The result of all this is that our economic system has been seriously injured; concessions must be made by all classes in the community. Wages must be lowered, but a fair and reasonable scale should be maintained; prices must be adjusted in proportion to cost of production. The public, which has suffered from the profiteering tactics of both labor and capital, will then aid in the restoration of prosperity by an increased interest in national welfare; it will help to turn the wheels of industry by judicious spending.

SUCCESS in all his relations with labor gives Mr. Henry Ford's remarks, in a recent issue of 'System', considerable weight. He takes as his text the truism that the employer should strive to understand his men; he must not make the mistake of thinking of them merely as units or as wage-earners, or as being different from himself; he must realize that they have the same desires and the same ambitions that he has. All of us want to succeed, and when the employer views his employees in this light he is courting efficiency. He begins to see that the success of his workman and the success of his business are tied together, and he will try to discover means that will help his men to succeed. A man who works with enthusiasm and interest will earn more for his employer than one who is indifferent and discouraged. Mr. Ford's advice to all employers of labor would be this: "Remember that your workmen are human beings; they have ambitions to succeed exactly as you have; give them a chance to serve their own interests in serving yours. Make them valuable to you by giving them a chance to become valuable to themselves." There must be some

logic in Mr. Ford's philosophy, for his company has weathered the industrial crisis without distress. In spite of rumors to the contrary, the work has been carried on, with only a comparatively short break, without borrowing; the output of machines last month reached a peak; and the prices, to the purchaser, are on the decline. It cannot be doubted that much of this success is due to the attitude adopted by the company toward its employees.

OVERTURES have been made by Mr. J. F. Callbreath, secretary of the American Mining Congress, to the president of the American Institute of Mining and Metallurgical Engineers with a view to a consolidation of the 'Journal' and the 'Magazine' respectively of those two organizations. We were aware of this fact two months ago; it is now announced officially, and it is interesting. Apparently neither publication is on a safe basis, owing to the high cost of paper and printing, and each may desire the support of the other. The proposal, we assume confidently, will be rejected by the Executive Committee of the Institute. The two organizations cover entirely different fields and their publications have little in common. To consolidate them would stultify both. The Congress essentially is a political organization, using 'political' in its honorable sense as covering public affairs, whereas the Institute is a professional society intended to promote the solidarity and contribute to the technical knowledge of those engaged in directing mining and metallurgical operations. The chief function of the Congress is to maintain a lobby at Washington in behalf of the mining industry, and it does this work admirably, thanks to the sagacity and energy of Mr. Callbreath, who is the key-man of the Congress. The chief function of the Institute is being subordinated to its publishing activities, which already have taxed its financial resources unduly. The Mining Congress 'Journal' has a reasonable excuse for its existence, because Mr. Callbreath has a considerable volume of legislative news to issue to the members of his organization. He might issue such news to them, as he does to the press, in mimeographed form, and thereby save the cost of much printing and of expensive paper, to which is added the additional expenditure incurred in the printing of pictures and piffle concerning various and sundry people of secondary importance. As a member of the Congress we feel entitled to say this much, but it is to be noted that the 'Journal' of the Congress does not deal with the technology of mining and metallurgy; it aims as much as possible, we are informed, to avoid trespassing upon the field so adequately covered by the technical press. The Institute 'Magazine' fails to observe this restraint and endeavors to compete commercially with the technical press, to which, incidentally, it owes its very origin, for the Institute made its start under the guidance of the first two editors of the 'Engineering and Mining Journal'. We refer, of course, to Rossiter W. Raymond and Richard P. Rothwell. It would make them turn in their graves to learn that there was such a thing as the Institute 'Magazine' and that it was now proposed to commercialize the energies of the

Institute further by a consolidation with the political publication issued at Washington.

Quiet Times

The curtailment of copper production, as might have been expected, has brought gloom to the mining districts of Arizona and Montana. At Miami, the Inspiration mine is shut-down, but the Miami company is producing, having a contract with the International smelter, near-by, but idle. About 8000 tons of concentrate already is stored in the smelter-yard and is covered by a shed to protect it from the wind. At the Calumet & Arizona a production of 500 tons daily is being made for a time, this output being bedded at the Douglas smelter. Operations at the New Cornelia are on a scale of 25% normal, and 1200 tons of ore is being produced daily. Two shovels are at work. At Bisbee the new mill of the Copper Queen is approaching completion and is said to do great credit to its designer, Mr. H. Kenyon Burch. At many mines the interval of inactivity is being utilized for research, more particularly in the making of leaching experiments. At Butte it seems like Sunday all the week, but about 5000 men are obtaining part-time employment. The month is divided into three parts, so that three sets of men work ten shifts apiece. The Anaconda company is paying for 1850 shifts daily, including the staff. Before the War there were 14,000 men employed at Butte, and during the War the number increased to 18,000. The Anaconda reduction works gives employment to 3000 men in normal times; now only 300 are engaged. The only part of the plant that is active is the zinc concentrator, which is being operated at quarter-capacity, equivalent to 400 tons daily. At the last census Anaconda had a population of 12,000. It was a thriving and thrifty community, and that is why the 'slump' has been met in such good spirit. The savings and current accounts in the local banks show that \$4,500,000 is on deposit. Needy cases are being assisted by the Red Cross and by the company "on the hill", but as yet no large measure of distress has developed. At Butte also, despite the months of near-idleness, the withdrawals from the savings banks are almost negligible. It is said that since Montana 'went dry', on January 1, 1919, there has been a marked increase of thrift among the workers. The population of Butte, including its suburbs, was never more than 60,000, and now it is about 50,000. Day's pay to the miner is \$4.75, a decrease of \$1 from the wartime rate. Contractors used to make \$7.50 to \$8 per shift. The second wage-cut, made in many mining districts, has been delayed by the shutting down of the Butte mines, but it may be anticipated that when full operations are resumed, wages will be on a lower scale. What work is being done now is mainly in the interest of the community. Most people are ready to believe that copper-mining centres like Butte are 'dead'; they seem somnolent, indeed, but there is a good deal of life, economic as well as social, to be seen, and, it is pleasant to add, there is a courage to face difficulties and a quiet confidence in the future of the industry.

The Outlook for Domestic Silver

Just a year ago the Re-purchasing Clause of the Pittman Act became operative for the first time. The Act, passed in April 1918, consisted of two distinct parts: the first authorized the melting of silver dollars, then stored in the vaults of the Treasury, to meet a national emergency; the second pledged the Government to purchase newly mined domestic silver at \$1 per ounce, in amount equivalent to the total contained in the coins melted. The first provision probably kept the price of silver from soaring to an unprecedented height in 1918, and consequently was to the disadvantage of the miner; by way of compensation the second stipulation, manifestly favorable to the miner, was made; but it was specifically arranged that the Government should not lose a cent by the dual transaction. On June 7, 1920, the price of silver on the open market fell below \$1, and on the following day it collapsed to 84 cents; automatically the Government was confronted with its obligation to purchase metal offered at \$1 per ounce. The Director of the Mint, after a brief delay for formulating the affidavits of the miner, smelter, and refiner as to the domestic origin of the bullion offered for purchase, began to accept consignments. That was almost exactly a year ago. During the last twelve months the Director has received 58 out of 209 million ounces that must be purchased to replace the dollars melted in 1918. It is no exaggeration to say that the operation of the Pittman Act has preserved the mining industry of the United States; but for it many of the mines that are now producing lead and zinc ores rich in silver would be in the unfortunate position of the zinc mines whose ore contains little or no silver and of the copper mines that have suspended production entirely. The silver mines in which silver is the predominant metal likewise would have suffered seriously, although they are not as important a part of the mining industry as are the mines wherein silver, under normal market conditions, is a secondary product.

The producers of American silver, consciously or unconsciously, are speculating on the probable duration of the period of fixed price. Financiers in New York, and, as a corollary, politicians in Washington, have agitated for the repeal of the Pittman Act. Congressman Louis T. McFadden, the advocate of relief to the gold miner, even went so far as to introduce a bill with this purpose in view. However, the silver miner need have little apprehension concerning the fate of such legislation, for two reasons: such a repeal is undesirable from every point of view, not for the producers of silver alone but for the country at large, and accordingly is not likely to evoke appreciable support in Congress; and, even if it were supported, the Congressmen from at least six Western States are so emphatically opposed to it that they would defeat the measure by a filibuster, should it become necessary to resort to such tactics. The possibility of a repeal is too remote for serious consideration. It is conceivable that the price of silver in the open market might exceed \$1 per ounce; in that event purchases under the Pittman Act would

cease automatically, for the obvious reason that domestic producers would sell their bullion elsewhere than to the Mint. Some peculiar combination of economic forces may result in an excessive demand for silver, but so far as can be foreseen the foreign price will remain well below \$1 for several years. Excluding both of these contingencies, the question of the further operation of the Pittman Act then depends entirely upon the length of time that will elapse before the remaining 151 million ounces of silver will have been mined, smelted, refined, and delivered to the Mint. At the present time competent authorities estimate the rate of production to be not greater than 40 million ounces per annum; some say less than 35 millions. In 1920 the production was 56,555,560 ounces, 95% of which came from seven States. The following data show the approximate output from each, in millions of ounces: Montana 13.5, Utah 11.5, Idaho 7.5, Nevada 7.5, Arizona 6, Colorado 5.5, and California 1.5. Of Montana's production 7 million ounces came from the Anaconda company's copper ore, 1.2 millions from the other copper ores of Butte, and 1.8 millions from the Butte & Superior company's zinc ore. From none of these sources is there any production at present. Of the remainder, 2,000,000 ounces was derived from zinc-silver ores mined by the Anaconda company, 358,000 came from the Hibernia mine of the Davis-Daly company, and the remainder was divided between Senator Clark's Elm Orlu mine and some fifty small mines in the old silver districts adjacent to Helena. Even assuming an increase of activity in the outlying districts, it is apparent that Montana's production is dependent largely on the revival of the market for copper and zinc. In Utah the situation is different. During 1920 the Utah Copper Company produced only 257,000 ounces of silver, the high-grade lead-silver ores of Park City, Eureka, Bingham, and other districts accounting for at least 95% of the total output. One of the largest silver producers in the country during 1921 should be the Tintic Standard mine, situated north of the town of Eureka. The company recently has commenced operations at its new chloride-roasting and leaching plant for the treatment of the low-grade ores, and the gross output for 1921, including high-grade shipping ore, will probably exceed 3,000,000 ounces. A moderate production from Idaho is being maintained largely by virtue of the high silver content of the lead and lead-zinc ores of the Coeur d'Alene region, although the Callahan company has suspended production entirely. Except for the Nevada Consolidated at Ely, most of the Nevadan properties are typically silver mines; three-quarters of the output comes from a little group in the Tonopah district. Here output is temporarily stopped by a strike of miners and craftsmen; but, when the labor troubles have been adjusted, it may be expected that the West End, Tonopah Extension, and Tonopah-Belmont, each with an annual output of between one and two million ounces during 1920, will renew their steady flow of metal to the Mint. On the other hand, the Tonopah Mining Company, once leader of them all, has reserves for only five months,

according to a statement made by its officials. Arizona is like Montana except that it has no mines supplying high-grade zinc-silver ore to help in maintaining the production; all the copper mines are practically shut-down except the Miami, whose ore contains very little of the precious metals. Arizona therefore plays an inconspicuous part, for the time being, in maintaining the output of silver, although a revival of gold-silver mining in the district of which Kingman is the centre seems likely; this will offset to some extent the loss from the copper mines. The lessee seems to flourish in Colorado. Hundreds of shippers are sending small consignments to the smelter at Leadville, thereby augmenting the output recorded by the larger mining companies. Freight-rates have militated somewhat against shipments, but no great increase in the rate of production is to be expected. Most of California's 1,500,000 ounces comes from a remarkable little mine called the California Rand in the southern part of the State; from this property, high-grade ore averaging 100 ounces of silver per ton is being shipped regularly to the smelter at Selby, on San Francisco Bay; moreover, we understand that the erection of a mill is planned to concentrate the low-grade ore that has been developed during the past two years.

Ore-reserves do not perpetuate themselves, and when ore containing a million ounces of silver is taken from a mine there is that much less to stope. The production of many thriving properties will diminish, or even cease, during the next two or three years. On the other hand, some small mines of today will grow into big ones to compensate in part at least for the diminishing production elsewhere. It is possible that one of our Silver Hills, or Broken Hills, or Silverhorns may develop into another Tonopah, but even so, it takes time to make big productive mines out of prospects. It is apparent that the most important factor in determining the duration of the Pittman Act is the time that will elapse before the markets for copper and zinc revive. However, we believe that the silver miners themselves join us in desiring an early termination of the prevailing general depression in base-metal mining, even if the result be a shortening of the period during which the Director of the Mint will purchase their silver at \$1 per ounce. Most of them prefer general prosperity even though it may seem contrary to their immediate interests. In analyzing the problem, the fact should not be overlooked that several months elapses from the time the copper or zinc ore is mined until the contained silver is ready for the market. This 'lag' between production and marketing operates both during the period when mines are shutting down and when mining is being resumed. Accordingly the result of the suspension of copper mining in April has not yet been reflected in the Mint statistics. On the other hand, it will be three or four months after production is resumed before the result will be noted in the increased production of refined silver. Everything considered, we feel safe in predicting that domestic silver will bring the producer \$1 per ounce for at least two and a half, and probably for three years.

DISCUSSION

Gold in Black Sand

The Editor:

Sir—In his communication on this subject, which appeared in your issue of May 14, Mr. Holmes evidently has been led astray by failure to realize that the statement of the results of certain tests made on heavy sands recovered in placer clean-ups in Alaska, to which he refers, was one of a series of similar tests that were undertaken for the purpose of devising, not an ideal means for the recovery of gold from such material, but some simple and easily applied method which would meet the conditions existing at the place where this material is produced.

The original report bore the title 'Recovery of Gold from Black Sand by Classifier Concentration', and gave the results of a test in which classifier concentration was employed. Any inference from this report that this method was regarded as an ideal method for the treatment of such material is altogether unwarranted.

Mr. Holmes is evidently not familiar with conditions existing in the interior of Alaska, and is therefore unaware that 'black sand' is a local term applied to any heavy sand recovered in a placer clean-up, regardless of whether or not it is black. As the investigation was made for the purpose of aiding local placer men in Alaska, it seemed warrantable to use a local term, even though it was susceptible of misconception.

The purpose of the investigation was not simply to recover the gold contained in this so-called 'black sand', but to ascertain some method whereby the placer miner could, without too much expense, either in the way of labor or additional equipment, make a better saving on this material. The Alaska placer miner does not entertain the same view as Mr. Holmes in regard to the great value of material containing 11 cents per pound in gold. It is true that the obvious inference from the preliminary determinations was that the gold was locked up in quartz and could be freed from it by grinding. However, the operators are not provided with grinding equipment, and while it would have been satisfactory to turn it over to a Chinaman for treatment, as suggested by Mr. Holmes, this method was unfortunately impracticable, because no Chinaman is to be found within a thousand miles of the place.

An elementary knowledge of transportation conditions in Alaska would suffice to indicate that shipping this material out for treatment would not produce a net return that would warrant taking the time to sack and ship it. The situation is very much like that of a farmer

who, having picked and prepared his apples for shipment, finds himself with a few bushels that are not of sufficiently good quality to warrant their shipment to market and yet which are too good to throw away. It is easy to point out that such fruit could be taken to a cider-mill and made into a liquid of interesting possibilities, but it is not worth the farmer's time to hitch up his team and take this material to the mill. He will probably do one of two things—either feed them to the pigs or leave them on the ground under the trees as material that, though possessing some value, is not worth the expenditure of further labor.

As regards the last table, I must plead guilty of contributory negligence in not having made it perfectly clear in the text that the assay of 0.73 oz. per ton of the canvas concentrate, represents an assay of that material after it had been amalgamated as described. The concentrate before amalgamation, of course, had a much higher gold content, as shown by the fact that bullion from this and the minus 6-mesh concentrate contained over 81% of all the gold in the original material. In other words, the table is misleading in that the terms used—concentrate and tailing—refer to the products of the classifier and canvas-table treatment, although the results given represent those products after amalgamation. The products shown in this table are really all waste materials, with the exception of the bullion.

The installation of grinding machinery at the placer mines of interior Alaska is at present not warranted, as operations are conducted on a small scale. It must be remembered that sand with a value of 11 cents per pound is not very attractive to the Alaskan placer miner. It was the object of these tests to recover as large an amount of the gold in as high a grade of concentrate as possible with apparatus that could be built at the mine. The operator is not interested in a method of treatment that he cannot duplicate. If the sand can be roughly concentrated in home-made apparatus (such as a classifier and canvas table for example) further work is justified on the concentrate, such as treatment by amalgamation.

In the test under discussion, by classification and canvas-table concentration, the concentrate produced amounted to 16.8% by weight of the original material* and contained 89.2% of the gold. The value of this concentrate was 55½ cents per pound, which the Alaskan placer miner can afford to amalgamate when he cannot afford to amalgamate 11-cent sand.

*These concentrates weighed 123½ lb. instead of 132½ lb. as given in the 'Mining and Scientific Press'.

Finally, it must be remembered that the sand work conducted at the Alaska station is with the definite view to gold recovery from sands that are now a waste product in interior Alaska, and that any treatment of such material must take into account the fact that only small amounts of 'black sand' are produced.

JOHN GROSS,

Metallurgist, Bureau of Mines.

Washington, May 31.

Regeneration of Cyanide During Precipitation

The Editor:

Sir—Mr. Algernon Del Mar's article in the issue of June 11 re-opens a matter of interest that caused me to trespass on the hospitality of your columns in 1913, when I expressed disagreement with the contention that free cyanide is regenerated during the passage of gold- or silver-bearing cyanide solution through zinc-box or press.

I took charge of a milling-in-cyanide and all-sliming plant in Africa in 1912 at a time when operations were disorganized by the circumstance that the precipitation of gold from the cyanide solution was very unsatisfactory. Being a newcomer I did not feel inclined to make sweeping changes without due consideration of local conditions. I was not in favor of the scheme of treatment. The ore was unusually rich in gold, and I considered that it should have been milled in alkaline water and efficiently amalgamated before being subjected to cyanide treatment. Other objections to commencing cyanide treatment in the battery were obvious, but I was in no position to alter the flow-sheet; all I could do was to concentrate my efforts on an attempt to reduce the amount of gold in the solution that was circulating.

I first found that diminution in the rate of flow through the zinc-boxes had no favorable effect; additional zinc surface also resulted in no appreciable reduction in the amount of gold in the tail solution. The boxes were packed and re-packed without an evidence of appreciable improvement. The trouble seemed to be in the solution; I therefore examined the records, but found that the amount of free cyanide in the inflowing solution was no less than it was when precipitation was satisfactory.

For some years previously I had come to several conclusions in connection with the testing of cyanide solutions; that Liebig's method of direct titration, with KI indicator, of a working solution containing zinc compounds was unreliable; that efficient solution control was an important factor in securing results; and that facilities and cleanliness were essential to accuracy. The last-mentioned conclusion may seem superfluous, but as a matter of fact I had found that neglect in this respect was common. I then looked into the question of how the cyanide control tests were being made, and found that the work was in the hands of a busy shift-boss, and that cleanliness of operation was impossible of achieve-

ment under the conditions that prevailed. The test for free cyanide was being made by the time-honored and world-wide method of measuring out a portion of the solution, adding a few drops of potassium iodide indicator, and then titrating direct with standard silver nitrate solution—the same method that Mr. Del Mar describes in his article. I had my suspicions that the estimation was in error, and I fixed up a separate laboratory where it would be possible to carry out testing work under proper conditions and in anticipation of some degree of accuracy of result. A complete series of tests was then made, disregarding the usual method, and estimating total cyanide (using alkaline potassium iodide indicator), protective alkalinity (using Green's method, with phenolphthalein indicator), and free cyanide (using neutral potassium iodide indicator, after the neutralization of the protective alkalinity as indicated by the previous test). A further analysis of the solution showed an abnormally high amount of zinc and some copper. The outstanding feature of the result was the fact that the amount of free cyanide present was shown to be far below the amount indicated by the routine tests made at the works; there was insufficient free cyanide to ensure effective precipitation of the gold. This, coupled with the high zinc content, was evidently the cause of the trouble. The ordinary test resulted in the inclusion of a proportion of double cyanide that varied in amount with the degree of alkalinity, this amount of double cyanide being reported as free cyanide.

The trouble was eventually overcome by a temporary raise in the actual free cyanide strength of the solution entering the zinc-boxes, to ensure complete or nearly complete precipitation, followed by the daily discharge of a small amount of barren solution with the residue—to decrease the amount of zinc in the solution and to permit the resumption of a normally low free-cyanide strength throughout the plant. I then wrote an article on the subject, which you were good enough to publish in the issue of September 20, 1913, in which I attacked the ordinary method for the estimation of free cyanide. I mentioned that, with an excess of free cyanide and a moderate alkalinity in the solution entering the zinc-boxes, this method will indicate more free cyanide at the tail than at the head of the box. In other words, the solution will appear to have a higher efficiency after the formation of more potassium- or sodium-zinc cyanide! I cited the fact as an evidence of the absurdity of this method of testing, showing that ultimate fouling of solutions may be entirely due to the addition of zinc as a concomitant of precipitation. I also gave the following figures of actual titration results of a normal solution entering and leaving the zinc-boxes:

	Incoming, %	Outgoing, %
Total cyanide	0.175	0.175
Free cyanide:		
Direct titration after addition of KI indicator, by usual method	0.145	0.150
Titration after neutralization of protective alkalinity as estimated by Green's method.....	0.120	0.095

The article in question elicited a generous measure of criticism, most of which, unfortunately, was irrelevant.

Its publication served one good purpose, however, and that was to bring to daylight a method of testing devised by E. M. Hamilton, and since adopted to a wider extent as a direct result of the attention drawn to it.

In all cases, both before and after my South African experience, I have been convinced of the inaccuracy of the ordinary test as a means of estimating free cyanide in the presence of zinc compounds; my impression is—and I am willing to admit that others, including Mr. Del Mar, may hold opposite views—that no appreciable amount of free cyanide can be regenerated during the precipitation of gold and silver by zinc; an indication that such is the case is, in my opinion, an indication that the method of testing is at fault, the apparent increase being due to the higher alkalinity resulting from the precipitation of the metal and the dissolution of zinc, thus:

and the action of the silver nitrate on the double cyanide, in the presence of this additional alkali, thus:

Leyner Drill

The Editor:

Sir—I venture to submit brief remarks concerning two points raised in your issue of May 28.

(1) In your editorial on Mr. Brunton it is stated that the Leyner drill first came into prominence in the driving of the Roosevelt adit. This is hardly correct: it had been most successfully used, and had become widely known, in the driving of the Newhouse and other adits around Idaho Springs several years before. In fact, the Leyner drill was virtually a product of the Newhouse tunnel; new patterns were successively tried out there, often following suggestions made by the Tunnel staff, and especially by S. A. Knowles, who was for many years in charge of work in the heading.

I think the Leyner drill was one principal cause of the very low costs of driving the Newhouse tunnel in 1906 and 1907: costs which I think have never been equaled under comparable conditions. Another cause was the system of drilling the round with a bar, set up across the muck-pile, a system which, so far as I know, was first used at the Newhouse tunnel, and which was rendered possible by the Leyner drill.

The illustrations of Roman and Phoenician objects found in workings at Rio Tinto, which accompany your interview with Mr. Brunton, remind me that, when a boy, I received in change, in the plaza at Rio Tinto, a bronze Roman coin, still in circulation! I do not guarantee that it had been in circulation ever since the days of the Roman Emperors. Probably it had been found in a hoard of some kind.

(2) Mr. Knapp's description of a method of prospecting, for surface pockets of gold, is interesting and clear. But I do not think it is correct to say that it was first developed in the foot-hill counties of California. In 1898 and 1899 I assisted an old colored prospector in finding a surface pocket, using this very method, in White county, Georgia. He dug out and I panned two or three hundred dollars' worth of gold in one day—which, by the way, completely exhausted the find. The old colored man informed me that he had been taught this method of prospecting by his father, and that it was commonly used in North Georgia before the (Civil) War.

GEORGE E. COLLINS.

Denver, Colorado, June 6.

Suspension of Assessment Work

The Editor:

Sir—The following request was sent to Senators and Representatives of Arizona, at Washington:

"Hon. Dear Sir:

"The Prospectors and Miners of Mohave county, Arizona, are unanimously opposed to any legislation pertaining to the postponement of annual assessment work, on mining claims, for the following reasons: Work for 1920 is already done, and work for 1921 is now in operation. Suspension of assessment causes hardship on the prospector that depends on that kind of work for a living, and grubstake to do his own work with. Now that most of the big mines are closed down, miners need this work; it retards mining development, which is now at a low ebb. It can benefit the non-resident slacker only, the suspension has already done much harm to the legitimate prospector. Kindly fight against any attempts at new regulations."

Engineers, miners, and prospectors that depend on the mining industry for a living should write their Congressmen and Senators protesting against any new rules, and let us see if we can't break up that clique trying to hold the public domain without doing the work. Already we have had four years of suspension, let us stop to think what that meant to the prospectors: let us say 40,000 mining claims were subject to suspension, at \$100 each that means \$4,000,000 a year, and for 1920 alone, or \$16,000,000 in all. Of course, we can excuse the war period. Now this money has been lost to both the prospector and the mining industry in general. Is there any wonder that the prospector is becoming extinct?

To illustrate the working of the annual suspension regulation: in the month of December 1920 the writer and others started in to do the assessment work on a number of claims for an Eastern company, for the year of 1920, as usual, before the suspension bill was signed, and we had got about one-half claim done when a wire arrived that President Wilson had signed the bill, so the agent representing the Eastern company came out next morning and told us to stop work.

Again, I personally know of several good mining claims held by outsiders that would be in the hands of respon-

sible men now and be working right along if the ground had become open in January 1920, as it ought to have been, but, No, it is yet held at least till July 2, 1921, if no other suspension intervenes. We all know that there is another set of prospectors regulations now pending before the Congress, so let us all stick together and try to have the bill defeated before it gets any further. I understand that the clique forced President Wilson to sign the last suspension bill at the last minute, but that I am sure won't work with the President this time.

Kingman, Arizona, June 8.

E. HEDBURG.

Copper Mining in Newfoundland

The Editor:

Sir—In looking through your issue of February 12, I was pleased to notice the following item: "Rumors of a sale of four hundred million pounds of American copper to foreign consumers, principally Germany, by the Copper Producers Association have been insistent in New York". The financing of this deal involves an outlay, it is said, of forty million dollars. This certainly looks encouraging for the copper-mining industry. I am also in receipt of information that the copper people have it figured out that there is but 16 years supply of copper at the normal rate of consumption in all the known deposits of the world, against 500 years of coal, and like comparison with other minerals.

The great so-called American deposits rated at 2½% copper are now proved to be but 1.75%. If this be so, 'Ye Ancient Colony' will come into her own in the year of our Lord 1937. Then, the large deposits that are now known to exist in the Great Bay of Notre Dame, such as the famous Tilt Cove mine, the Little Bay mine, the latter with good 6% ore at 1400 ft. deep, with little or no prospecting done either on the strike of the ore, or on the foot or hanging walls. The South West Arm deposits are rich in copper, assays from vein-matter have given as high as 30% copper. Some years ago, several hundreds of tons was taken from one deposit that averaged over 18%. The sterling Peyton deposit at Hall's Bay, a valuable property, the Sunday Cove Island property, and the Roberts' Arm deposit, and last, but by no means least, the Mother Lode mine, 14 miles inland from Hall's Bay, and which is known to prospectors as the Great Gull Lake deposit, the ore of which is chalcopryite, and is shown on the surface for over five miles east and west. The Great Gull Lake Copper Co. owns 16 claims, or locations, of one mile by a half-mile each, or, in other words, eight square miles of this great orebody. They have done considerable prospecting and development work on the property, and have opened up two of their claims by sinking shafts and cross-cutting. They have sunk 60 ft. on one claim, and cross-cut 75 ft., all in ore averaging 2.78% copper. On another of their claims they have sunk 45 ft. and have cross-cut 30 ft.; at this shaft the vein-matter gave assays at different depths of 9%, 12%, and 15% copper, the whole averaging about 5%, but the owners have not ascertained the full width

of the orebody, at either of the shafts, as the ore in the breast of the cross-cut is still good, and from surface showings the owners have every reason to believe that the orebody is considerably wider, and from surface indications on one claim it is over 1500 ft. in length east and west. On another part of the property there is a number of large and small boulders of copper-bearing rock, hundreds of tons in some pieces. Assays of samples taken from these pieces show 7.25% of copper with traces of gold.

And what about our goldfield on White Bay, when some few years ago a toy mill was erected and run by men who know something about copper mining, but absolutely nothing about gold mining or milling. Of course, it was a commercial failure. Why not? The employers put pieces of quartz in the crusher with visible gold in it, but after passing through the mill it was never seen again, and sights of free gold can be taken from the surface on other parts of the property, as well as in the shaft. It's a crime the way mining in this country has been butchered, and money flung away, so to speak, in the prospecting as well as in the actual mining, or working of the different deposits, by those who were sent here to look after their company's interest. Some were good capable men, but like every other good thing, were hard to keep; others were incompetent, and the only thing they seemed to be capable of looking after was their \$200 or \$300 per month, and when they had to leave for the Sunny South, they did their 'bit' to prevent capitalists from becoming interested in mining in this country. They are like the poor—always with us, but unlike the poor they do more harm than good.

T. E. WELLS,

President of the

Great Gull Lake Copper Co., Ltd.

Little Bay, Newfoundland, June 4.

Coloring of Glass

The Editor:

Sir—Answering the query of Francis Drake, in your issue of June 11, page 806: I have often seen violet-colored glass by the roadside in Nevada and elsewhere, and have assumed that the coloring was due to manganese. Here are a couple of formulas for glass-making that show manganese as an ingredient:

(1) 110 lb. quartz; 55 lb. potash; 22 lb. chalk; 1.5 lb. saltpetre; 1.5 lb. arsenious acid; 0.75 oz. pyrolusite.

(2) Pure silicious sand, 63 parts; potash, 22 parts; lime, 12 parts; oxide of manganese, 1 part.

Palo Alto, June 12.

W. H. SHOCKLEY.

THE general belief that the ancients were able to harden or temper copper to a greater extent than is now possible is a myth, in the opinion of the U. S. Geological Survey. Specimens of ancient so-called 'tempered' copper that have been examined have proved to be no harder than copper that is manufactured today, or to be simply an alloy of copper and some other metal.

THE NEW PLANT AS COMPLETED

The New Surface-Plant for the United Verde Copper Company

By L. A. Parsons

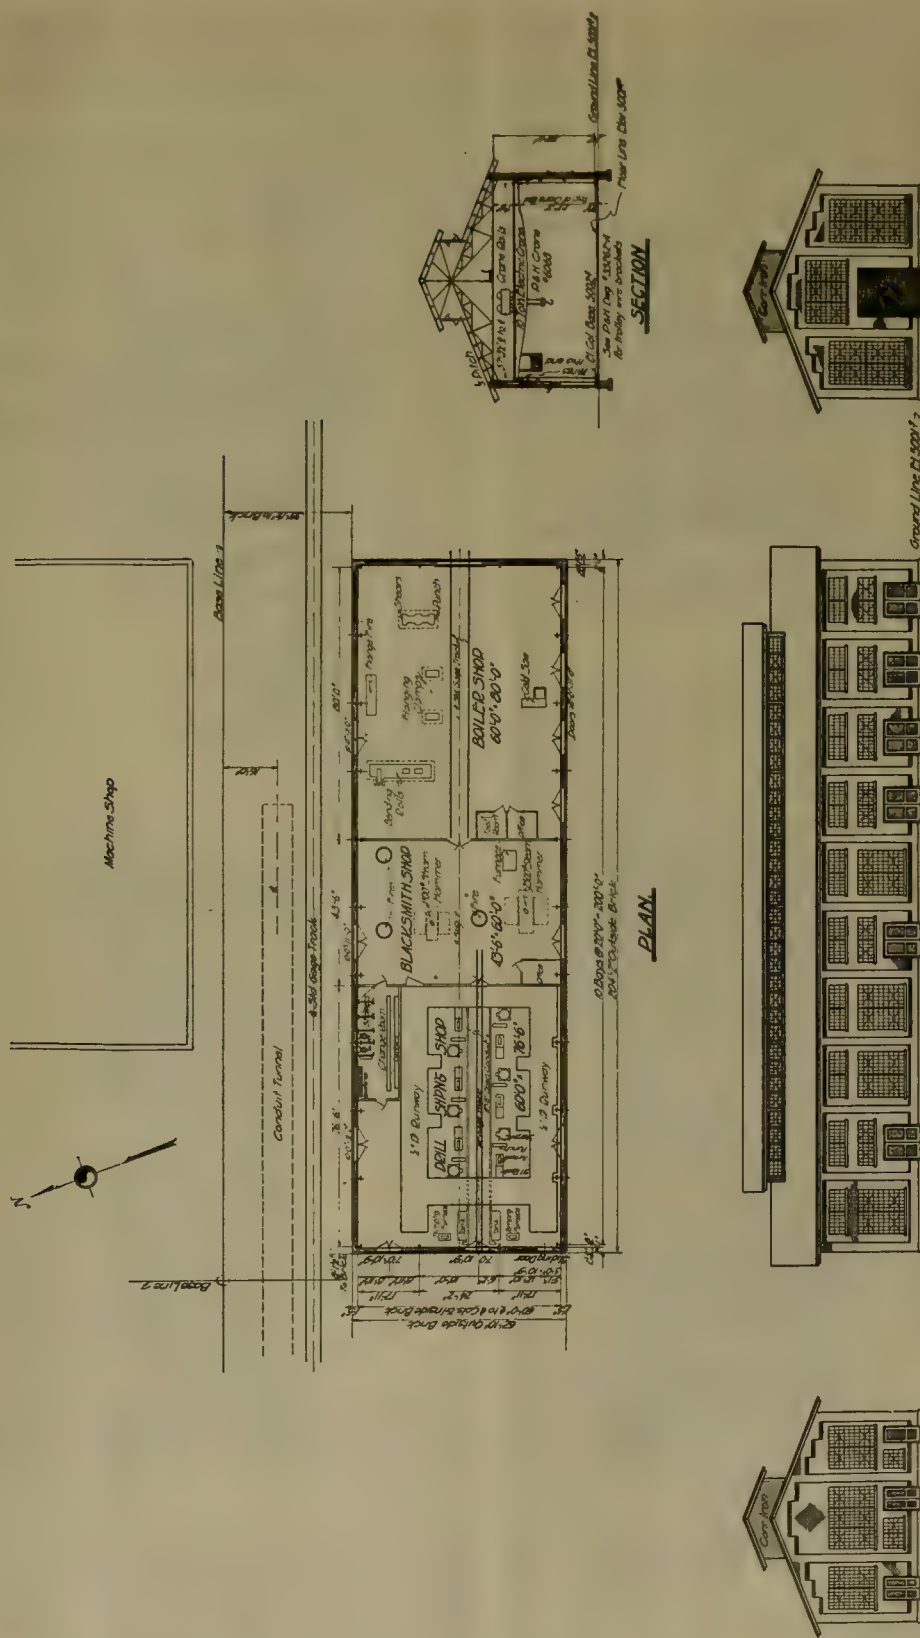

The present surface of the United Verde mine is on the eastern flank of the Black Hills, Arizona, at an elevation of approximately 5500 ft. The hillside is steep, dropping abruptly from the peak of the mountains, at an elevation of 7000 ft., to the Verde valley 3500 ft. below. Practically the entire terrain slopes so steeply that the erection of buildings is rendered exceedingly difficult. Natural horizontal areas are small and so scattered as to be almost useless for the purpose of construction. The town of Jerome adjoins the mine, but is in great part not owned by the company and is outside its direct control.

When the growth of the enterprise, together with certain changes in the mining methods, rendered the old surface-plant inadequate, and the housing of most of the employees in Jerome became increasingly unsatisfactory, the problem of building a modern surface-plant and of providing the employees with comfortable and attractive living quarters was not easy of solution. It was finally decided to 'make' ground on the hillside at the 500-ft. level of the mine, which is somewhat below the greater part of Jerome, to build the new surface-plant on the space thus provided, and to add gradually a modern town-site for employees adjoining the surface-plant. Entrance to the mine would be obtained by an adit connecting with an underground shaft (No. 6) for handling men and supplies.

The principal factors affecting the design of the plant were as follows: (1) An entire new plant was necessary, as the old one was not only unequal to the increasing de-

mands upon it, but the plans for mining the old fire-stopes of the mine by steam-shovel involved the excavation of much of the old site. (2) The plant must be capable of handling all the repairs and current construction work arising from the mining of 3000 tons per day underground, the operation of five steam-shovels on the surface, and the operation of the Verde Tunnel & Smelter railroad, connecting the mine with Clarkdale. (3) Space must be economized and yet room should be left for normal expansion. (4) Special attention must be paid to drainage, on account of the sloping ground. (5) Much of the ground being 'made', foundations for heavy machinery would require special work. (6) As the collars of the shafts were 500 ft. above, means of access to the mine needed to be provided for men, supplies, and repairs. (7) Weather conditions include strong winds; a high summer temperature, occasionally reaching 100° in the shade; light frosts in winter; and a small annual rainfall, but with occasional storms lasting two or three days.

Early in the design, comparative estimates showed that because of the increase in the price of steel, structures built of corrugated iron and steel would cost as much as those built of brick and steel. Consequently, the latter method of construction was adopted, resulting in buildings of unusual attractiveness and durability. Considerable care was taken to make them as attractive as possible in appearance, and, as can be seen from Fig. 2 and Fig. 3, the completed structures suggest far more those usually found in cities than at mines.

SOUTH SIDE ELEVATION

WEST END ELEVATION

BOILER AND BLACKSMITH SHOPS

The power-house, machine-shop, and boiler-blacksmith shop are all self-supporting steel structures. The face-bricks were furnished by the New Mexico Firebrick Co., of Gallup, New Mexico, and the common brick by the Los Angeles Brick Co. The walls on all buildings are 17 in. at the pilasters, and 13 in. between. All the other buildings have steel roof-trusses resting on brick walls. Concrete for foundations was a 1:3:6 mixture, and for floors 1:2½:5, reinforced by Clinton welded wire and some triangle mesh. Lupton steel sashes were used throughout, furnished by David Lupton Sons Co. The purlins are 8-in. channels with a 4-in. by 4-in. nailing-strip bolted in. All roofs except for the power-house and time-office are ½-pitch, and are made by nailing 1½-in. tongue-and-groove sheathing to the purlins, and covering this with red 'flatcrete' concrete tile made on the spot. The roofs of the power-house and time-office slope one inch in 12, and are made of a 2½-in. concrete slab on Hyrib reinforcing, covered with Johns-Manville roofing-felt, asphalt, and red 'Regal' roof-paint.

The details of construction and equipment of some of the more important buildings and accessories are as follows:

POWER-HOUSE. This is built on bedrock, so there was no trouble with foundations for structure or machinery. The equipment includes one 6800-cu. ft. Ingersoll-Rögler compressor (\$45,000 f.o.b. factory), one 1500-cu. ft. and one 3000-cu. ft. Ingersoll-Rand compressor from the old plant, and one 20-ton 3-motor electric traveling-crane. Two 500-kw. motor-generator sets are situated in the No. 6 hoist-station. The cooling-tower is 18 by 30, furnished by C. F. Braun & Co., San Francisco (\$3600 f.o.b. San Francisco). The air receivers are three old Parker boilers in the basement. Air is taken through a 16-in. line through the adit to a receiver at No. 6 shaft, thence by a 12-in. line down the shaft for distribution through the mine. The sub-station equipment includes four transformers and a 16-panel Westinghouse switchboard. The power-line from Hopewell is No. 4 B. & S. 7-strand hard-drawn copper cable, transmitting current at 44,000 volts. The pump-house is equipped with three 6-in. Cameron centrifugal direct-connected pumps, for the circulating jacket-water. A purifier and water-filter is used, manufactured by Wm. F. Scarfe & Sons Co., of Pittsburgh.

The machine-shop and boiler-blacksmith shop are on filled ground; hence the foundations required special work. Excavations for the column-piers were carried to bedrock and filled with concrete. Some of these holes were dug 25 ft. below grade-line before reaching solid footing. Reinforced concrete girders spanned between the column-piers to carry the brickwork. Machines were set on spread concrete footings, reinforced with scrap-iron, to distribute bearing on the fill. The fill had been in 16 months when the machines were set.

MACHINE-SHOP. This is equipped as follows. Many of the small machines were obtained from the shop at the old surface-plant.

- One 25-ton 3-motor electric crane.
- One 5-ton electric crane.

One convertible locomotive hoist manufactured by the Whiting Foundry Equipment Co. This consists of six jacks each with a capacity of 50 tons, the whole driven by a 50-hp. motor.

One 90-in. driving-wheel lathe, manufactured by the Niles Tool Works Co. The distance between face-plates is adjustable from 6 ft. 6 in. to 9 ft. 2 in. This is used principally for turning locomotive-drivers.

One 24-in. slotter, manufactured by the Niles Bement Pond Co.

One 26-in. by 12-ft. engine lathe.

One 36-in. by 16-ft. engine lathe.

One 42-in. by 42-in. by 12-ft. planer. These three were all made by the Niles Bement Pond Co.

One 36-in. by 44-in. side-head boring-mill, manufactured by the Niles Tool Works Co.

One 6-ft. radial drill-press.

One 400-ton hydrostatic press.

One 17-in. by 8-ft. LeBlond lathe.

One 3½-ft. radial drill-press.

One small drill-press.

One 28-in. shaper.

One 15-in. shaper.

One No. 3 milling-machine.

One 14-in. small lathe.

One abrasive-surface grinder.

One sensitive drill-press.

One drill-grinder.

One hack-saw.

Two emery-wheels.

BLACKSMITH-SHOP. The steel-sharpening equipment includes six batteries of sharpeners with the necessary punches and furnaces. The steel after being sharpened is carried over a steel-sheeted runway in cars with flangeless wheels to the end of the shop, where it is tempered in two furnaces and placed in racks for use in the mine as wanted. The steel will be carried both to and from the mine in specially built narrow-gauge cars. The boiler-shop contains one 1100-lb. steam-hammer and one 2500-lb. steam-hammer.

CHANGE-HOUSE. This is designed to accommodate 1400 men in addition to the foremen and shift-bosses. The clothes are hoisted up by overhead pulleys and flexible wire-rope. Each seat has a small individual locker for small articles. This is not hoisted with the clothes. In addition, each shop-building has an individual change-room, equipped with shower-baths, lavatories, and steel lockers. The time-office is attached to the main change-house.

WAREHOUSE. This has a basement, main floor, and balcony floor, a total of 17,000 sq. ft. of storage space. The shelving and lockers are of steel. The elevator is an Otis electric.

In addition to the buildings shown in the plan there is, opposite the warehouse on the warehouse-track, a storage shed for cement and other heavy material and an oil and gasoline storage. Concrete platforms on the track side of the warehouse and of these storage buildings are 8 ft. wide. All standard and narrow-gauge tracks are so

East Elevation

North Elevation

West Elevation

South Elevation

GENERAL MINE OFFICES

arranged that material can be transferred easily from one shop to another. All standard-gauge rails are 75-lb.

All steam-piping, water-lines, electric lines for both lighting and power, and air-lines are carried in a two-compartment conduit-tunnel with concrete service-boxes from the tunnel to each shop. The heating system is vacuum return-steam.

Sewage is carried to a 10-in. main sewer-line in a trench under the conduit, and thence down the hill to septic tanks. These tanks will also handle the sewage from the new townsite, which will be built adjoining the surface plant. When completed this will contain about 500 standard brick or hollow-tile dwellings, with stores, theatres, schools, and community centres. The streets will be graded and the sidewalks built of concrete. One hundred houses are to be built immediately. All will be fireproof, and will have baths, toilets, and sleeping-porches. A new road will be opened from Jerome through the new townsite, connecting with the present road from Hopewell to Clarkdale.

The hillside is trenched above the site to carry all surface water to culverts under the fill, which empty the water down the gulch. Mine-water from the adit empties into the sewer system.

The adit from the portal to the underground shaft (No. 6) is 1648 ft. long. It is 500 ft. from the sub-station to the portal. Men will be carried to the shaft in specially designed cars. Each car holds 26 men, and 10 cars are coupled together to form one train, thus carrying 260 men each trip.

The shaft is 13 ft. by 13 ft., and has one main compartment 8 ft. by 13 ft., in which operates a double-deck cage carrying 50 men on each deck, balanced by counterweight. The other compartment contains the manway, counterweight, and pipe-lines. The cage was made big enough and so designed that it can hoist the electric locomotive, thus obviating repairs underground. The cage-hoist is driven by a 350-hp. motor.

Table I gives some statistics on the construction. The steel was furnished by the Kansas City Structural Steel

engineer for the United Verde company, and under the supervision of C. M. Hoffman, superintendent of machinery.

In a paper recently read before the Institution of Mining & Metallurgy on 'Notes and Records of Mining Costs', A. E. Pettit stated that the zenith of efficiency on the Rand was probably reached about 1909. At that time the white labor was picked from a cosmopolitan group of miners and mechanics from all over the world, whose capability could not be excelled. The strike of that year robbed the field of many of the older men who were not parties to Union control, and led to a dilution of labor and the introduction of new fetters of trade unionism which diminished efficiency; and although by reason of the greater tonnage crushed the working costs did not show an immediate increase, expenses increased on account of the gradual growth of the inefficiency which today is so prominent. The crisis in white labor became acute in 1920. The number of men employed under trades-union regulation, and the inefficiency of this labor, caused costs to rise to such an extent that in spite of the premium on gold, it appeared inevitable that some of the lower-grade mines would have to close down. Conferences were, however, arranged between management and men, with a result that the number of white men was reduced and their efficiency increased. Wages were arranged on a grade-tonnage scheme, with the result that not only was the tonnage increased, but the grade was more than maintained. The following summary shows the results obtained at the Simmer and Jack mine:

	January 1920	June 1920	July 1920
Number of tons crushed.....	46,100	60,100	61,600
Mill grade (dwt.).....	4.926	5.730	5.608
Europeans at work.....	571	524	525
Tons per man.....	80.7	114.7	117.3

The gold recovered from silicious ore and tailing in California in 1919, according to the U. S. Geological Survey, was as follows: By amalgamation, 308,638 oz.;

Table I

Co., and after being fabricated in their shops was erected by their own men. The clearing of the site was done by the Twohy Bros. Construction Co. The United Verde company maintained a construction camp and boarding-house for the men employed on construction, charging \$1.25 per day for board, and furnishing a room free. The entire work was in charge of E. A. Hoff, construction

by cyanidation, 43,099 oz., a large part of which was from the treatment of concentrates; from concentrates and ore sent to smelters, 67,330 oz. These figures are only approximate, as many small operators keep no separate accounts and even the larger companies do not always segregate the quantity of gold obtained by the different methods of treatment that are adopted.

Manufacture and Uses of Tungsten

By W. E. John

*In its pure state tungsten has been comparatively unknown; it has been mentioned in connection with high-speed tools and the filaments of electric incandescent lamps; but today the metal is used for the production of electric contacts for the make-and-break of magnetos, and more generally for the contacts in connection with induction coils used in the ignition systems of a number of motor cars.

The metal is usually obtained from wolframite, FeMnWO_4 . There are, however, other ores, such as hübnerite, scheelite, and ferberite, that can be used. The ore is crushed, then reduced to a fine powder, then thoroughly mixed with Na_2CO_3 , care being taken that the soda is in excess of the WO_3 content of the ore. This mixture is roasted in a gas reverberatory furnace at a temperature of about 800°C . The result is the formation of sodium tungstate, Na_2WO_4 , a pasty mass which flows in a thick layer over the floor of the furnace. The floor is usually a cast-iron plate about 1 in. thick. The mass is raked out while hot, allowed to cool, and finely crushed.

It is then shoveled into wooden vats and agitated with hot water; the sodium tungstate goes into solution readily; it is filtered, and the saturated solution is passed into a precipitating tank. The clear liquid is heated by a jet of live steam to boiling temperature and is then treated with a solution of calcium chloride, CaCl_2 . A white precipitate, calcium tungstate (CaWO_4), is deposited. This is well washed and boiled with hydrochloric acid, giving a precipitate of tungstic acid, H_2WO_4 . This yellow precipitate is filtered and washed; usually it is found to contain 99.53% H_2WO_4 . This purity, however, is not sufficiently high for use in forming pure tungsten metal. The precipitate is therefore boiled with a solution of ammonium hydroxide and the result is, after filtration, a clear solution of ammonium-paratungstate. The solution is evaporated until a white mud of para-tungstate is precipitated, which is treated with pure nitric acid, giving a yellow precipitate of H_2WO_4 . It is again dissolved in ammonia and again treated with nitric acid, the repetition of dissolving and re-precipitation being necessary to get a sufficiently pure product.

This final acid product is fired in silica crucibles at a temperature of about 1000°C ., the water is driven off and the remaining powder, WO_3 , is bright yellow in color and is generally about 99.96% pure. The impurities may be iron, aluminum, and calcium in the form of oxides. As a matter of fact the metal that is produced from this tungstic oxide is of still greater purity owing to the volatilization of most of the impurities during the subse-

quent treatment. About 90% of the tungsten content of the ore is recovered.

The WO_3 is now reduced. It is heated to about 1200°C . in a closed furnace through which a continuous flow of pure hydrogen is passed. This reduction process leaves pure tungsten in the form of a dark-gray, fine, crystalline powder. The powder is stable under normal conditions. It will oxidize if heated in air and can be made to combine violently with sodium nitrate. If it is not completely reduced it has a bluish tinge, in fact at one stage of reduction it has a pleasing deep-blue color; this, however, must be avoided as the presence of oxide is fatal in the subsequent treatment.

The dark-gray powder is removed from the furnace after about seven hours of treatment, and is pressed in special dies under hydraulic pressure, which may be as much as 300 tons per square inch. The metal crystals adhere together to form a solid bar. These tungsten bars, usually rectangular in cross-section, will vary in size according to the size of the die used. A bar about $\frac{5}{8}$ in. square and $8\frac{1}{2}$ in. long weighs about one kilogramme with a density of about 15 to 17.

The pressed bar is now sintered in an electric furnace supplied with an atmosphere of hydrogen. The sintering heat is produced from the resistance of the bar itself. The temperature is about 3000°C ., which is built up in the bar in a few minutes. The heavy current necessary is usually provided from a special power-line through suitable transformers. The atmosphere of hydrogen prevents oxidation of the bar. The tungsten at this stage is in the form of a crystalline metal, heavy, that is with a specific gravity of about 17 or 18, and of a white silvery appearance. It is hard and generally with a smooth surface, but very brittle; in fact, it cannot be dropped from the hand on to the floor without danger of breakage.* Should water vapor be present in the sintering furnace the bar may come out with a frosted appearance.

For making rod the bar is heated to about 1250°C ., usually in an electrical resistance furnace, and is passed into a swaging machine and reduced in diameter by a series of dies until it is down to as small as 0.05 in. Usually, however, it is left at about 0.175 in. to 0.125 in. in diameter. It is now of great density, having a specific gravity of about 19.3. Should sheet or ribbon be required, the bar may be pressed and sintered in suitable rectangular shapes, or the rod, at any diameter, may be subjected to a hammering or rolling operation to flatten it.

The product now obtained is a pure metal rod, ductile and fibrous. It is said that with care it can be welded at a bright yellow heat, but, from my experience, I doubt whether a true weld is made.

*Abstracted from the 'South African Journal of Industries'.

Tungsten is difficult to work because it is dense and tough. In fact a scleroscope test would probably show only 40, compared with 100 for hard steel; but the hardest file will not stand up to it, nor will a drill pierce it. It will, however, readily fracture under percussion or shock. It will melt at about 3075°C. The tensile strength is usually over 500,000 lb. per square inch. As with many other metals, the tensile strength of small wires increases above the proportionate strength of the metal in the coarser sizes. At the same time it becomes more ductile the more it is worked. It is not affected by air or water under a temperature of red heat. It is practically unaffected by sulphuric acid, hydrochloric acid, nitric acid, or hydrofluoric acid. Concentrated mixtures of HCl and HF will attack it, as also will fused nitrates, peroxides, bisulphates, alkali carbonates, and caustic alkalis; solutions of these chemicals do not affect it.

In the Pointolite lamp the principal light-giving body is a single crystal of tungsten, generally shaped as a sphere about $\frac{1}{8}$ in. diameter. The feature of the lamp is, as the name implies, the emission of light from one point. Tungsten, owing to its high melting point, is the only metal that can be used in this connection. The light from this lamp can be focused better than the light from any other incandescent lamp. The lamp operates on direct current, and the tungsten ball is heated by the electric current, forming an arc in a vacuum or in a suitable non-oxidizing atmosphere between the ball, connected to one pole, and a coil of tungsten wire, connected to the other pole of the circuit. The coil above mentioned is first heated on a separate circuit to heat up the parts so that the arc will be supported between the sphere and the coil.

Tungsten is also used for loading golf balls. The core of the ball is made of tungsten metal powder. With this heavy material as a centre, a finished ball of the same weight and size as the usual standard ball may have room in its construction for a larger proportion of resilient material, thus giving a livelier ball without altering the finished size and weight.

THE electrolytic recovery of zinc is advocated as an economic proposition in Great Britain, by S. Field, in a paper recently read before the Faraday Society of London. The British spelter industry is at present depressed and there is room for an enormous increase in the output of zinc. Home ores should, if possible, be used; abundant supplies of low-grade and complex ores are available; they are not amenable to distillation but respond readily to alternative electrolytic treatment. Processes have been worked out to effect economic recovery; sulphide ores are calcined to oxide and a predetermined proportion of sulphate; the calcine leached with acid zinc sulphate liquors (3% Zn + 10.5% H₂SO₄) from the electrolytic cells. Special treatment avoids gel formation, and admits of high extraction and easy filtration. The lead-silver residues are sintered, and go to the blast-furnace for the recovery of argentiferous lead.

The zinc-sulphate solution is too impure for efficient deposition. High purification is an essential for subsequent deposition. The methods worked out are given in detail and comprise the use of oxidizing agents such as air, ozone, lead, and manganese di-oxides for the removal of Fe, As, Sb, and Co. Zinc-dust in a slightly acidified solution readily removes Cu, Cd, and Ni, greater speed of elimination being obtained with the elimination of Co by the prior addition of about 0.005 to 0.01% Hg as sulphate. Ni and Co constitute two insidious impurities. The purified liquors contain not more than 3 to 5 parts of Co and 0.2 part of Ni per 1,000,000. The pure neutral solution is acidified down to 8% Zn + 3% H₂SO₄ and electrolyzed between lead anodes (which in the absence of certain impurities are permanent) and aluminum cathodes. The liquors attain a temperature of 40-45°C. and the cells, arranged in cascade, absorb 3.35 volts and give a current efficiency of 90%. This represents about 3200 kilowatt-hours per ton of zinc cathodes. The out-flowing liquor is used cyclically for extraction and acidification. Subsidiary power is amply covered by 800 kw-hr. per ton. Hence 400 kw-hr. (160 kw. per ton cathode zinc per day) covers all power. The cathodes are melted and yield ingots assaying not more than 0.02% Pb, 0.02% Cd, and 0.01% Cu and Fe together, with at least 99.95% zinc. Purification is simplified if only a 99.92% product is required.

THE discovery of a new mineral in Madagascar, containing a comparatively high percentage of radium, is reported in the 'Berliner Tageblatt'. The account adds that "the world supply of pure radium is not exactly known, for it is distributed in tiny parts of grammes, milligrammes, and fractions of milligrammes, over countless clinics, scientific laboratories, and industrial works. Statistics which have some claim to accuracy speak, however, of 100 gm. The larger part—namely, 60 gm.—is in the United States, the chief productive soil for radium. The Memorial Hospital in New York possesses the tremendous amount of 4 gm. In Europe there are two centres of the highest radium standard—Vienna, which preserves 2 gm. at the Academy of Sciences, and Paris, which, since Christmas, has concealed the like amount in the cellar of the Radium Institute, conducted by Madame Curie. In order to curb the fiery forces of 2 gm., it is let into a great hollowed stone, which is, moreover, clothed in a mantle of lead 30 centimetres thick. This repository of radium is said to resemble an image of Buddha. It is kept in a walled-in safe, which is closed by a heavy iron door. One gramme of the stock in the United States was presented recently to Madame Curie.

THE Australian total of 943,692 oz. of gold for 1920 is the smallest since the discoveries of the 'fifties, states a consular report. The largest on record was in 1903, when the total for Australia alone was 3,836,095 oz., and for Australia and New Zealand together, 4,315,841 oz., of a value of £18,340,563. Practically the whole of the 1920 output has been exported.

The Kantishna Mining District, Alaska

By James A. Haney

INTRODUCTION. The Kantishna mining district is situated north of Mt. McKinley and comprises some 650 square miles of the Yukon watershed, extending from the head of the Kuskokwim river eastward to within a few miles of the Government railroad. This railroad, when completed, will connect Seward on the coast of Alaska with the navigable waters of the interior, furnishing an all-year means of transportation for this district as well as for other districts farther inland. All of the mining activities of this district, both lode and placer, are confined to a range of mountains called the Kantishna hills, and prominent lode-locations have been made in an area some two miles wide and about 28 miles long. These so-called hills are rugged mountains of considerable size and are known as 'hills' only because of their nearness to the towering peaks of the Alaskan main range. At the mouth of Eureka creek, which is almost due north of Mt. McKinley, Lat. $63^{\circ}30'$ north, Long. 151° west, is the office of the U. S. Commissioner and Recorder; also the Kantishna post-office, which at present is the centre of mining activities in this district. Kantishna and Glacier City, a small cluster of cabins some 20 miles to the north, constitute the only settlements within the district.

ROUTES OF TRAVEL. This district is reached in summer by steamer up the Kantishna river 140 miles to Roosevelt landing, then 30 miles overland to Kantishna, or from Roosevelt landing 35 miles to Glacier. In summer and in winter the district is accessible by boat to Seward, then by rail to the end of construction, then by pack-horse in summer, or sleighs in winter, some 70 miles to the diggings. River navigation opens about the first of June and closes the first of October. A wagon-road is under construction from Roosevelt landing, and a survey is being made for a wagon-road to the nearest point on the railroad.

Freight on ore from this district to Tacoma or San Francisco averages about \$65 per ton. This includes a land haul of 30 miles and insurance charges. All labor is paid \$5 per day with accommodation; the mess cost is about \$3 per day per man.

POWER AND FUEL. A good grade of lignite can be obtained by a haul of from 10 to 20 miles. No permits have been taken out to develop this coal and no work has been done. As there is considerable overburden, little can be seen, except a few outcrops in the creek-beds, one seam about 10 ft. thick is exposed in the bed of Mosse creek, and lies flat. The quality of this lignite and the physical conditions offer encouragement to development, and a generating plant at the mine should be a source of reliable and cheap power. There are several hydro-electric power possibilities that could be de-

veloped to supply power for six months in the year and two or three that possibly could become available for a longer period. Representatives of two different companies have applied for permits to develop some of these

ROUTE TO KANTISHNA DISTRICT, ALASKA

water-powers. Scrub-timber can be had for fuel from the southern slopes of the mountains, but for mining-timber it would be necessary to go to the lower river-bottoms, a distance of from 10 to 15 miles.

TOPOGRAPHY. The mining area is characterized by sharp rugged mountains cut by narrow V-shaped valleys that radiate in all directions from the higher peaks, and with few benches or other evidences of heavy erosion. The elevation above sea-level is from 1200 ft. in the valleys to 5000 ft. at the summits. In summer this district is well watered by the many small streams that flow from the high mountains. The surface is covered with a white Caribou moss to the tops of the mountains and the lower levels are covered with a tundra and coarse bunch-grass that forms what are called 'nigger-heads'.

GEOLOGY. The Kantishna hills are made up chiefly of a highly metamorphosed schist, with an occasional igneous intrusion. The schist is mentioned by Capps, of the U. S. Geological Survey, as the Birch Creek schists, which are said to be "the oldest rocks seen in the region."* All the larger veins so far located cut the schist and have a general strike of N. 60° E. and dip at an angle of from 50° to 90° SE., and the preliminary work indicates that these veins are persistent in strike and dip.

LODES. The first lode locations in this district were made by the placer miners, the discovery being made on the highest parts of the Kantishna hills where the absence of any overburden made prospecting the easiest. No real development work was done on these locations until the Great War brought on the high price of silver, which greatly encouraged development work. The general search for silver brought into the district many old-time quartz prospectors and they quickly traced many of the lodes to the creek-levels and made many other discoveries of importance.

The more important minerals that have, so far, been recognized are gold, silver, galena, gray copper, stromeyerite (copper-silver sulphide), chalcopyrite, stibnite, sphalerite, arsenopyrite, and pyrite; all these minerals are considered primary ore, but in places at the outcrop there is a shallow oxidized zone in which secondary minerals exist, such as lead carbonates and iron oxides. Any of these primary ores may be found in almost pure bunches, or they may be intimately intermingled. The stromeyerite, gray copper, and galena carry the most silver, and constitute the shipping ore. Last year one property shipped 500 tons of ore that assayed 180 oz. silver, 18% lead, and $\frac{1}{4}$ oz. gold per ton. The low percentage of lead was due to the fact that most of this ore came from near the surface and was much oxidized. This same property this year will ship about the same tonnage, but assaying 70% lead, 130 oz. silver, and $\frac{1}{4}$ oz. gold per ton. One other property will ship ore this year, and from the prospects and the development work being done there should be four properties shipping ore in the summer of 1922.

PLACERS. The first placer mining in this district was done in 1906 and all the alluvial mining to date has been open-cut work. The usual method is to ground sluice the 'muck' and top gravel to within a foot or so of bed-

rock, the remaining gravel and some of the bedrock being shoveled into the sluice-boxes by hand. In this way only the shallow creek-valleys could be worked and up to the present time no attempt has been made to work the deeper bench-gravels that are known to carry gold. However, this year the hydraulic plants are being installed in the district, one on Moose creek at the mouth of Eureka and one on Caribou creek about 10 miles to the north. Some native silver is found by the placer miners and in at least one place heavy galena ore (float) is so plentiful as to clog the sluice-boxes.

PRODUCTION. The total production of placer gold to date is about \$400,000, and the total production from the lode mines is roughly \$200,000. There has been no record kept of the placer output and the estimated gross production is arrived at by a comparison of the estimates furnished by men who are intimately acquainted with the work done on the different creeks where gold is recovered by this method.

FUTURE. The future of placer mining in this district depends on the successful working of the lower-grade gravels by hydraulic or other methods, and the importance of the Kantishna as a lode-mining district depends on favorable results of development with depth. The low-grade sulphide ores may require some experimentation before a milling process is selected, but the Kantishna district offers no great difficulty to successful mining, provided a considerable tonnage is developed. The bonanzas are always the first to be exploited in any new camp and are a powerful magnet attracting men and establishing transportation. The new Government railroad ought to stimulate the mining activities of this district.

In the prefatory note to the reports on gold, silver, copper, lead, and zinc, issued by the U. S. Geological Survey, Edson S. Bastin draws attention to the fact that, in the mining industry, these five metals are closely related in both the genesis and the geologic occurrence of their ores. They also hold together in mining and in metallurgical treatment. Of their ores some contain all five metals, many contain three or four, and few contain only one. Gold and silver, for instance, on the one hand, and lead and zinc on the other, almost always stand in close genetic relations, and the ores of each two are usually mined together. Copper ores almost invariably produce some silver and gold as well as copper, and lead ores, with certain exceptions, produce notable supplies of silver. Zinc ores in the Western States contribute also to the production of silver. In the same mine sometimes, and in the same mining district frequently, all five metals occur in commercial quantity. This situation is recognized by the U. S. Geological Survey in its publication of the annual reports on the mineral resources of the country. Hence the general treatment of each of the five metals in the general reports and the grouping together of the related metals in the various mines reports descriptive of individual or geographically grouped States.

*Capps, S. R., 'The Kantishna Region', U. S. G. S., Bull. No. 687.

The Silver Horn District, Near Pioche, Nevada

By T. H. M. Crampton

The Nevada Silver Horn mine is situated in the camp of Silverhorn, Lincoln county, Nevada, about 23 miles north of Pioche, and 100 miles south of Ely. It is about 45 miles north-east of the old camp Delamar, and four miles from Bristol Wells, which was a town of 3000 inhabitants in 1876. A copper smelter was in operation for some years at Bristol Wells, as well as a mill for treating the silver and copper ores from the surrounding district. All that is now left is the slag dump and three bee-hive charcoal ovens.

The first discovery in what is now known as Silverhorn was made by John L. Whipple, a cow-man living at Sunnyside. While hunting for a stray horse, he was attracted by the massive outcrop, which projects from 10 to 30 ft. in places. He took a sample, which was assayed in Ely and gave returns of 103 oz. silver per ton. Mr. Whipple lost no time in returning to the ground and locating it. This time he took more samples; one he crushed, sending part of the pulp to two different assayers. The returns checked and showed 438 oz. of silver per ton.

As he was getting ready to open the property Mr. Whipple secured a satisfactory offer and sold his interest to George Waddell, of Newcastle, England. The mine was operated but a short time when Waddell died. Apparently none of his heirs realized its value, or they were not in a position to look after the property, and Mr. Whipple bought it again at an attractive price. He subsequently disposed of the property to Crampton & Crampton, engineers of Santa Monica, California, and they in turn interested J. C. Weir, of Weir Bros. & Co., of New York, who sent Thomas H. France to examine the mine. Upon his recommendation the first systematic development of the property was begun in February of this year.

The outcrop was cross-cut and trenched at intervals of 50 ft. and sampled in width of from 10 to 90 ft. As the work of sampling the deposits progresses it is found that they are even more extensive than had been anticipated. To date approximately \$20,000 has been spent in this work and about 1000 samples have been put through the assay-office. Development so far has proved the existence of a replacement orebody which varies in width from 10 to more than 200 ft., and which has been exposed for a length of over 2000 ft. The strike is nearly east and west, and the vein dips to the north at about 23°.

The quartz occupies a position between a brown lime-shale hanging wall and a dark-blue limestone foot-wall, which is hard and compact. There is evidence of extensive movement along the contact of these formations, which resulted in a brecciation of both. The breccia was replaced by solutions carrying silica and silver. Gener-

ally throughout the extent of the outcrop the replacement has been complete; an average analysis of the ore shows 92% silica, with little iron or other impurities. There are occasionally found large masses of the original breccia which was never replaced, and which appears as 'undigested' masses irregularly scattered along its longitudinal extent.

Prof. Charles P. Berkey, of Columbia, a well-known petrographer, recognized in the many samples submitted

NEVADA

that "deformation continued after some of the silicification had been accomplished and shattered a part of the rock that had been already silicified. The mineralizing solutions that penetrated these later fracture lines of weakness healed them with vein quartz from the same source that had silicified the limestone, and toward the end of the operation furnished ore minerals, among which is a variety of silver-bearing minerals. There are no less than five or six of these ore minerals, all very intimately associated and ranging from sulphide in one extreme to the chloride of horn-silver on the other. Whatever is done with the ore must take this association

into account". This feature makes the new district of particular interest to engineers.

Across the outcrop at right angles to the longitudinal extent or strike are to be noted frequent shear-zones. These are the result of movement subsequent to the first mineralization and quartz replacement; they are the points that received the second introduction of primary minerals. These shear-zones are the richest areas along the outcrop. At one place the shear-zone is about 55 ft. across, while others range from six feet in width to 30 feet.

The fact that two-thirds of the outcrop is sheared makes the development of these zones of great interest. J. Nelson Nevius, of Pasadena, has been retained by the

Thomas H. France is consulting engineer for the company. It is under his direction, and with his co-operation, that Frank A. Crampton, manager for the company, is blocking-out ore. Upon completion of this development work the company may erect a mill, the capacity of which will be governed by the available ore disclosed. There have been many estimates of the developed ore, but the company has made no formal statement regarding this. However, it is believed that several hundred thousand tons which will average 17 oz. silver is reasonably assured.

The Silverhorn district is by no means a one-mine camp. The Silver Dale mine, which adjoins the Silver Horn on the west and is controlled by C. Walter Geddes, has the extension of the main vein-system and the showing of ore is favorable. A number of outcrops, similar in character to those found upon the large properties, are being prospected. The district has been visited by no less than 25 engineers, and the general opinion is that the disclosures of silver ore are larger than any heretofore discovered in the State of Nevada.

Silverhorn is ideally situated at an elevation of about 6200 ft., with water piped to the camp from a spring that furnishes about 30,000 gallons per day. There are many trees over the hills, so that wood for domestic use, and for small mine-timbers, is abundant. The nearest railroad point is Jackrabbit, on the narrow-gauge line running from the Los Angeles & Salt Lake railroad to Pioche. There are now more than 60 frame buildings, tent-houses, and stores in the camp, and the population in three months has grown to over three hundred.

FIFTEEN years ago Malaya produced more than 60% of the world's tin; today the figure stands at less than 40%, according to the 'Far Eastern Review'. In 1903 Bolivia was credited with under 10,000 tons; today that country is the second largest tin-producing country of the world; official estimates give it 20 to 25% of the total output. Nigeria, whose output 10 years ago was practically negligible, is returned in official statistics as producing in 1917 nearly 10,000 tons. The Malayan production in 1919 is given as 36,867 tons, compared with 50,000 tons five years before. The loss on Negri Sembilan output is more than offset by the gain in Pahang, while the loss on Selangor is easily cared for by the gain in Perak. Although the percentage comparison of Malayan output with the world's total has fallen, owing to greater production elsewhere, the actual output has considerably increased. Production has been affected by years of war restrictions and hindrances; present figures do not indicate the real strength of Malayan ore production; there is good ground for urging that the industry should be taken more carefully into consideration. At present there is one large and well-known American mining company (Yukon Gold) in the Federated Malay States. This firm is importing large quantities of material and sending out capable men as prospectors. As a result, many of the local mining corporations are taking a keener interest in scientific mining.

THE NEVADA SILVER HORN OUTCROP

Nevada Silver Horn company as geological engineer, and under his direction a number of new disclosures have been made. These discoveries have been based upon the defining and locating of the shear-zones. It is of interest to know that the first introduction of mineral, which took place during the silicification of the breccia, carried silver into practically the entire mass to the extent of about five ounces per ton. The ore in the shear-zones will probably average between 15 and 30 oz. silver per ton. It is believed that at least one-quarter of the entire body will make profitable milling ore.

High-grade silver ore is frequently found and samples running as high as 3685 oz. have been secured, but the possibilities of the Silver Horn are based upon the large tonnage of milling ore now being blocked-out.

WORLD'S PRODUCTION OF COPPER, IN TONS

at its smelters. Expenses throughout the whole organization have been drawn down to a minimum. Three wage-reductions of 50c. each have been made. At its new zinc-oxide plant in Columbus, the company is operating at about 50% capacity, or a production of between 3700 and 3800 tons of lead-free zinc oxide annually.

ONLY FIVE COPPER COMPANIES ARE PAYING DIVIDENDS

Only five copper-mining companies today are paying dividends. They are Utah Copper, which lately cut its quarterly dividend from \$1 to 50c. per share; Phelps Dodge, now paying \$1 quarterly; Miami, 50c.; Calumet & Arizona, 50c.; and United Verde Extension, 25c. per share. All these companies have closed their mines, except Miami. That producer is operating at close to capacity, making its metal for less than 12c. per pound and it carried no unsold metal over into 1921. Being low-cost producers, these mines were able to sell considerably more metal on the decline in the price of copper during the last six months than the others. They all finished 1920 with relatively large surpluses of net current assets and they have, therefore, been able to continue dividends longer than the rest.

CALIFORNIA

Downieville.—Thomas Brannigan, recently appointed superintendent of the Kirkpatrick mine, has a gravel-mill ready to commence operations. Ventilation in the mine has been improved by connecting with the old Magnolia tunnel.

Georgetown.—New machinery has been installed at the Grit mine. Three shifts of miners are employed under the direction of Walter King. New machinery has been purchased for the Argonaut mine, between Georgetown and Greenwood, which was recently purchased by Sacramento capitalists.

Grass Valley.—At the special meeting of the Mine Workers' Protective League held on June 19 and attended by more than 600 men, it was decided to submit a counter proposition to the mine operators, offering to accept one-half of the \$1 cut proposed, to go into effect on July 1. This would make the wages \$4.62½ for miners and \$4.25 for shovelers. It was decided to call a mass-meeting of all citizens for a public discussion of the question from all angles; the mine operators will be invited to attend.

Although the proposed new wage-scale of the leading mines here was rejected by the Mine Workers' Protective League, it is announced that it will be put into effect on July 1. At the North Star property it was stated that the management was preparing to close the mine in the event of the employees not caring to work for the wage offered, which is \$4.25 for machine-miners and \$3.75 for shovelers. The mines taking the lead in the matter are the North Star, Empire, and Idaho-Maryland, the latter being in process of re-opening. The smaller properties will follow the lead of the larger operators.

Redding.—Platinum and iridium are being mined on Beegum creek in the south-western part of Shasta county. Twenty-five men are doing well, making from \$10 to \$15 per day. The creek is staked for seven or eight miles. Pans and rockers are used in washing-out the metals. The great trouble now is that the water is too high, due to the snow melting in the mountains.

Sonora.—A mill is being completed at the National mine near Groveland. New equipment also includes two marine-type gas-engines, a hoist, and a compressor. Adits, shafts, and winzes aggregating 1000 ft. have been driven to develop the property. The mill is expected to start about July 15.

Tin Mountain.—George Allen, Arthur Smith, and B. B. Foreman have entered into a contract with the Tin Mountain Mining Co. to develop the nine silver-lead claims of that company and work has been started. These three men have a contract to work for one year, taking their wages in stock at a rate of 5000 shares monthly. All of the stock in the company is owned by William Foreman and J. B. Kendall of Goldfield, with the former holding a large controlling interest. The claims are 20 miles south of 'Death Valley' Scotty's ranch and are in Inyo county. A 23-ft. shaft has been sunk in the vein and a drift is being driven from this into the mountain, gaining depth rapidly. Five tons of \$154 ore was saved in sinking the shaft and several tons assaying \$165 has been saved in driving the drift, which is 20 ft. long. The width of the vein is not known; the ore-shoot is 20 in. wide at the face of the drift.

Weaverville.—Lewis Gardella, the Oroville dredge operator, has contracted to purchase the Paulsen ranch at Lewiston on the Trinity river. The place contains 300 acres. It has been thoroughly prospected by drilling, so the gold con-

tent of the gravel is known. Gardella has commenced the construction of a dredge. The Star Dredging Co. had an option on the farm a few years ago and commenced to assemble material and machinery, but its enterprise was abandoned.

COLORADO

Aspen.—Operations are shortly to be resumed at the Annie mine as a result of the discovery in the Hope tunnel. The Annie is believed to be situated on the same vein, but higher up the mountain by 1600 ft. An examination of old workings disclosed considerable ore in sight and in filled stopes with the dump containing a large quantity of low-grade mill ore. A 50-ton mill on the property equipped with ball-mill, concentrating tables, and flotation unit will be put in shape to treat low-grade silver-lead ores.—The Hurricane company is planning to develop its properties in this section by cross-cut from Hope tunnel.

Breckenridge.—Under instructions from the main office at Kansas City, the Wellington Mines Co. shut-down its mines and mills on June 15. About 40 employees were affected. No reason was given, but the shut-down is understood to be due to the price paid for zinc. The company was the heaviest producer of zinc ore in the county. The ore mined carried from 25% to 48% zinc with some silver and lead. Dividends paid to date total \$1,950,000.

Cripple Creek.—Traffic has been resumed over the Midland Terminal and Midland roads and ore accumulated during the temporary suspension of service is being moved in trainloads to Colorado Springs for treatment at the Golden Cycle mill.

Leadville.—The tunnel of the Leadville Mines Development Co., to which enterprise citizens of Leadville have subscribed in excess of \$27,000 at \$1 per share, has been driven to date beyond the 350-ft. point in wash and is now believed to be entering the Weber grits and shale. A raise was carried through for ventilation at a point 289 ft. from the portal. The tunnel is projected to exploit the Canterbury hill territory, and is carried 5 by 7 ft. in the clear with a drainage-box on one side.

IDAHO

Coeur d'Alene.—After expending more than \$50,000 during the last two years, the Columbus Mining Co. has closed a contract with the Union Iron Works of Spokane for new machinery. The property consists of 15 claims in the Murray section close to the Jack Waite. The lower adit has been driven 550 ft. and another 500 ft. of cross-cut should tap the first vein on the Tributary creek side fully 800 ft. below the outcrop. E. P. Gallagher is manager.

B. N. Sharp, of Spokane, is driving an intermediate tunnel in the Nabob mine. The distance between the main Nabob level and the Denver level is 236 ft.; the tunnel is about half way between these two levels.—At the Sidney property 60 tons of first-class shipping ore is stored in the bins. This will be moved to the smelter as soon as a tramway can be installed.

Work on the new 50-ton concentrator at the Yankee Boy mine on Big Creek is progressing. Timbers are on the ground, grading has been completed, and most of the machinery received. Shipments are going forward at regular intervals and several sets of lessees are taking out the ore. The Sunshine company, operating the mine, is driving a long cross-cut adit to intercept the Yankee Girl vein.—Stockholders of the North Bunker Hill Mining Co. have elected the following directors: Elmer Brown, N. T. Hardy, A. W. Van Guilder, F. C. Cartwright, J. L. Trowbridge, and J. E. Gunn. Development work is proceeding from the 500-ft. level of the main shaft.

Hailey.—E. W. Ring has 100 men employed at the Independence and North Star Mines in the Wood River section.

A small vein recently discovered assayed 100 oz. silver and 60% lead. Work has been suspended on the North Star orebodies, awaiting further metallurgical tests in the treatment of the complex sulphides of zinc, lead, and silver along with gold ore.—Oscar Hershey, employed by the Bunker Hill & Sullivan company, is engaged on a comprehensive investigation of a number of old mines in the district. Among these are the once famous May Flower, Goned, Red Elephant, Idahoan, Eureka, Red Cloud, Minnie Moore, and Queen of the Hills, all heavy shippers in their day.

Lewiston.—Robert N. Bell, former mine inspector of Idaho, who has made examinations of copper properties along the Idaho side of the Snake River canyon, 100 miles south of here, says that diamond-drill development has disclosed large quantities of primary copper-sulphide ore carrying precious metal. Assays of 3% copper and \$4 in gold and silver have been obtained.

Pearce City.—The Bloyer Mining Co. began operation of its new mill on June 1. The ore is free-milling, worth from \$13 to \$25 per ton. The new plant includes a 25-ton Chilean mill, a 75-ton Downey crusher, and a steam-power plant.

MICHIGAN

Houghton.—Copper is again moving rather freely out of the Lake Superior district in spite of the fact that just at present there are few inquiries for the metal. Most of the copper moved within the last two weeks represented business placed some time ago, although some 'spot' metal was included. Three large cargoes, totaling 5,000,000 lb., have been taken out. The first of these shipments, amounting to 1,800,000 lb., was made up of 500,000 lb. of Calumet & Hecla metal, the remainder being divided between the Copper Range and Quincy smelters. The Michigan smelter handles Copper Range, Mohawk, and Wolverine copper. With the exception of 156,000 lb. for export, the metal was consigned to domestic points, including 300,000 lb. of Calumet & Hecla copper for Detroit. Of the export metal, 112,000 lb. was Calumet & Hecla and 44,000 was Copper Range business. The second cargo, 1,600,000 lb., was Calumet & Hecla copper for export to Germany. The third shipment, 1,600,000 lb., was made up of 1,200,000 lb. of Copper Range copper and 400,000 lb. from the Quincy smelter. Of the Copper Range metal, 600,000 lb. was for export. In addition to the above, Calumet & Hecla has shipped two carloads of copper to Illinois consumers.

Calumet & Hecla still has a considerable amount of mineral and mass copper on hand at its smelters, which will be held in reserve in the event any more orders are received from abroad for special shapes or sizes. This will obviate the necessity of re-smelting copper already refined. Calumet & Hecla keeps six furnaces in commission. At present they are employed in smelting cupola blocks, making anodes for the electrolytic plant where the silver and impurities are removed. The copper is then returned to the smelters in the form of cathodes and refined.

In the Calumet & Hecla and subsidiary mines, advantage is being taken of the shut-down to make essential repairs. Some shaft work is under way and attention also is being given to surface plants and machinery. At Lake Linden some work has been done on the big dredge at the reclamation plant. Little timbering has been found necessary in any of the Calumet & Hecla or subsidiary shafts and underground conditions so far as timbering is concerned are good. When mining is resumed it will be necessary to do some timbering immediately, but this work will not take long and can be done without undue interference with production. In the meantime, Calumet & Hecla is shipping in timber, about 100 carloads having already been delivered.

The ground being encountered in the Kearsarge lode penetrated by the cross-cut from the 81st level of the Red Jacket

shaft of the Calumet & Hecla is described as neither "good nor bad", nevertheless the work will proceed until it is proved definitely one way or the other. The drifts, both ways, are now in a total of 400 ft. The good 'rock' is being taken out and put in a stockpile near the shaft for a mill-test later. Only a small force of men is employed on this work.

In the Mayflower property, the south cross-cut from the 1700-ft. level is still in vein matter. The east drift, however, is getting into trap. The 'rock' opened in the south is of encouraging character.

MONTANA

Butte.—The Davis-Daly company is blocking out ore on the 2300 and 2700-ft. levels of its Colorado mine. The company is in position to hoist 400 tons of 5% copper ore daily.—The East Butte company is operating its mill and flotation plant seven days per week instead of five days as was the program several weeks ago. Ore received from the Davis-Daly company assists the East Butte in maintaining operations.

Marysville.—At the bottom of an 80-ft. shaft in the Etna mine Lawler Brothers are reported to have uncovered a 2-ft. vein of gold ore that assays \$60 per ton. The Etna was formerly known as the Mexican mine.

NEVADA

Arrowhead.—Mark G. Bradshaw, consulting engineer, has started sampling the Arrowhead to determine whether the ore exposed justifies the building of a mill. It is estimated that 750 to 1000 samples will be taken. The shaft, now 330 ft. deep, may be sunk another 100 ft. as a result of the sampling.

Eureka.—It is reported that the Eureka-Uncle Sam Mining Co. has purchased the patented claims and bonded four unpatented claims which formerly all belonged to the Hamburg Mining Co. The Uncle Sam adit is in about 630 ft.; a late sample from the face assayed \$49.80. Work will soon be resumed in a drift from the adit, now in 200 ft.—Adams hill now looms up as the most active part of Eureka district. The Eureka Holly Extension Co. has begun operating, with S. C. Scott as superintendent. A new hoisting plant has been brought in from Elko and will be installed at the Standard shaft, which is 300 ft. deep. Surface prospecting at about 100 ft. south-west of that shaft has resulted in finding a fissure 18 in. wide, which carries ore that assays 56% lead, \$2.06 in gold, and 42 oz. silver per ton.—The Eureka Prairie Mining Co. has purchased and made the first payments on Marguerita, Fraser and Molino, Morning Star, Macon City, and Lone Star mines, on Adams hill, all of them producers of gold and silver and amenable to treatment by straight cyaniding. The company is cleaning out and laying track in the Marguerita adit. Trucks are in use hauling the timbers and building material purchased by the company at Buckhorn.—At the Eureka-Holly mine the 400 and 500-ft. levels are producing high-grade ore. A raise is being cut from the 600-ft. to the 500-ft. level, for better ventilation, as well as to prospect for the continuation of some high-grade ore that was mined on a limestone-porphry contact.—During the last two weeks the Richmond-Eureka company shipped 20 tons speiss, and the Eureka-Croesus and Eureka Nevada mining companies each shipped four cars of ore to the Utah smelters.

Klondyke.—There is 2000 tons of ore awaiting shipment in the Klondike district, according to testimony given at a hearing before the State Public Service Commission in an action brought by the Tonopah & Goldfield railroad to suspend service to and from Goldfield and Tonopah. It is reported in Tonopah that the Belmont company hopes to be able to accept custom ores soon. It is said the mill

is to be re-started in a short time, which will bring relief to the Klondyke shippers.—The bins and all available workings in the Knox are filled with ore. This company continues drifting east on the 65-ft. level and, after re-opening the shaft to 145 ft., a drift is being driven east at this depth toward the ore-shoot.—The McSherry sub-lease on the Original Klondyke recently shipped 12 sacks of high-grade ore and last week 52 sacks of \$237 ore was shipped from the Goldman sub-lease.—There is one ton of \$1000 ore sacked at the Maupin sub-lease, with several hundred tons of lower-grade ore on the dump. Charles Brandon of Goldfield has a contract for sinking the Ben Hur shaft to

The Old Atlas Mill Near Sneffels, Colorado

150 ft. and he has started work. Several lessees on the Ben Hur have opened ore.

Tonopah.—The force of state police that was at Reno prepared to go to Tonopah has been demobilized on receipt of notice from Nye county officials that they were not needed for strike duty. The situation in Tonopah has been quiet recently. The companies are reported to be having trouble training the men imported from the coast. The Tonopah Extension mill has been re-started.

OKLAHOMA

Picher.—The following mining companies suspended operations during the week of June 12; Lucky Jew, Monarch, Black Eagle, Manhattan, Niangua, and Royal. With zinc 'ore' quoted at approximately \$20 per ton, other mines are likely to suspend operations.

UTAH

Eureka.—The Tintic Standard Mining Co. has made a favorable settlement with the Federal Government as regards income taxes for the years 1916 to 1919, both inclusive. The amount claimed by the Government was \$360,000 over and above what the company had already paid, and this sum was reduced to \$84,031. This reduction comes as the result of several months' work on the part of the company's engineers, who convinced officials that the depletion reserve, as estimated December 31, 1917, and based on the actual net value of ores, amounted to \$4,150,000 instead of \$1,800,000, as first set down. Recently a new orebody has been uncovered on the 1100-ft. level. The company's milling plant is treating from 140 to 150 tons per day, with highly satisfactory results, according to E. J. Raddatz, president.

Conditions at the Little May property, in the south end of the district, are reported as encouraging, by John Matson, manager. Recently a streak of ore was opened up, which is from 18 to 20 in. wide, with average returns of \$1.40 in gold, 18.3 oz. in silver, and 6.5% copper. Owing to the high sulphur content of the ore, a favorable treatment charge has been secured from the Tintic Milling Company.

Shipments of ore from this district for the week ending June 11 totaled 137 cars, as compared with 119 for the previous week. The Tintic Standard shipped 56 cars; Chief Consolidated, 37; Iron Blossom, 8; Eagle & Blue Bell, 7; Iron King, 6; Colorado, 6; Swansea, 4; Victoria, 4; and Gemini, 3.

Park City.—Shipments of ore from this district for the week ending June 11 totaled 1009 tons, of which the Judge allied companies shipped 405; Silver King Coalition, 382; and the Ontario, 221.

Salt Lake City.—The United States Smelting Co. has notified shippers of silver-lead ore that the reduction in freight-rates on bullion from Utah smelting points to the Atlantic seaboard, amounting to \$5.50 per ton, will be passed on to producers as soon as they become effective. This will mean a saving to the shippers of one cent per ounce of silver and 4c. per pound of lead and copper.

According to figures made public by the United States Geological Survey, this State produced 97,454 oz. of gold, 13,106,976 oz. of silver, 116,931,238 lb. of copper, 140,838,113 lb. of lead, and 8,157,739 lb. of zinc in 1920. With silver at an average price of \$1.09 per ounce, copper 18.4c. per pound, lead at 8c. per pound, and zinc at 8.1c., the value of the above output was \$49,744,334, as compared with a total of \$45,169,328 for 1919.

After a rather explosive hearing before the State Securities Commission on June 16, on the petition of the Bingham-Galena Mining Co. to sell 467,100 shares of treasury stock, the Commission took the application under advisement and a decision will be rendered shortly. The Bingham-Galena was incorporated for 1,000,000 shares. The property now consists of the old Silver Shield holdings, for which 300,000 shares were paid. Two additional tracts were purchased, one for 50,000 shares and the other for 70,000 shares. Silver Shield stockholders, under an option, subscribed for 13,000 shares additional at 15c. per share. When the Utah Power & Light Co. recently cut off power service at the mine in default of a bill of about \$700, an additional block of 7500 shares was sold. It is proposed to make a contract with George Graham Rice to underwrite the 467,100 shares, and to such a proposition a number of the stockholders objected, on the ground of the bad reputation of Mr. Rice as a promoter. James A. Hogle, the well-known financier of Salt Lake City, told the Commission that "he believed it would be most unfortunate for the Silver Shield and for Salt Lake City to have George Graham Rice come here at this time to undertake the financing of the Bingham Galena

project". The decision of the Commission is awaited with interest.

One of the most destructive, as well as spectacular fires in the history of Utah, occurred at North Salt Lake on June 11-12. About 5:50 p.m., on June 11, a bolt of lightning struck a huge steel tank, with a wooden roof, on the property of the Utah Oil Refining Co. In an instant the 1,500,000 gal. of distillate was a seething furnace, and dense clouds of smoke ascended to a height of five or six thousand feet. The city fire department, assisted by employees of the oil company, succeeded in keeping the flames confined to the large tank until 7:30 a.m., June 12, when it exploded, with deadly results. Three employees of the oil company were either killed outright or died as a result of their burns, while 45 others, mostly city firemen and oil company employees, were injured. Burning oil was scattered for a radius of a quarter of a mile, and it was deemed advisable to remove the 105 patients from St. Marks' hospital, about two blocks distant, to other hospitals in the city. Most of these patients were employees of the various metal and coal-mining companies of Utah. Immediately following the explosion, several smaller tanks were set afire, and it was not until nine or ten hours later that the flames were brought under control. J. C. Howard, president of the oil company, estimates the loss at \$350,000. The Utah Oil Refining Co. plays an important part in the mining industry in Utah, as practically all of the metal mines using flotation secure their oil from the plant, in addition to their lubricants.

Santaquin.—At present the Syndicate mine is working two shifts, driving the adit into a promising vein in the south-east fissure. The tunnel is now in 2145 ft. and is at a depth of 300 ft. below the surface. Benjamin H. Bullock is manager.

Tooele County.—Development at the Pennuva Copper mine is encouraging, according to J. B. Christensen, who is in charge. This property is situated in the Silver Zone district. In the south shaft, 16 in. of ore, averaging 75 oz. silver, has been discovered.

WASHINGTON

Deer Trail.—A contract has been let to haul ore from the old Queen and Seal mine; 125 tons of high-grade silver ore is sacked for shipment. In the early days the mine is said to have produced a profit of over \$300,000 in one season.

Kettle Falls.—At the Silver Queen group a cross-cut tunnel has been driven 1070 ft., intersecting the Silver Queen vein at a vertical depth of 400 ft. The vein contains silver.

BRITISH COLUMBIA

Prince Rupert.—By unanimous judgment the Court of Appeals has dismissed the appeal brought by the Premier Gold Mining Co. against the decision of Judge Young, of the Prince Rupert County Court, in which a miner named Caskie was awarded \$77, being wages at \$5.50 per day from the time that he arrived at the mine until the earliest date that he could return to Prince Rupert. There are 22 other claims of a similar nature against the company. During the strike last year the manager came to Prince Rupert to engage labor, and, as men refused to go to the mine to engage as strike-breakers, he assured them that the strike would be settled when they got over to the mine. The strike, however, was not settled, and the men refused to go to work. The strike was settled 52 days later, when Caskie went to work for the company. He brought suit against the company for the 52 days during which he was idle, but was awarded wages for only two weeks, it being impossible for him to return to Prince Rupert during that period.

The Drum Lummon Mines, Ltd., has been reorganized and has changed its name to the Douglas Channel Mines.

Ltd. The new company has a capital of \$3,000,000, and the shareholders in the old company will receive share for share in the new company, with the understanding that the shares are to be pooled for two years. The Glenville A. Collins Engineers, Ltd., are to receive 600,000 shares, in consideration for which they are to liquidate all the debts of the old company, to build a wharf, sink a winze 100 ft., and drive 200 ft. on the vein; all of which must be completed within 15 months. Fred G. Jarret has been appointed superintendent of the mine, and work at the mine will be re-started at once.

The Belmont-Surf Inlet Mines, Ltd., expects to have its new mine, the Pugsley, ready to start production within the next two months. The company has been developing this mine for some time and has demonstrated the existence of a large body of high-grade ore, said to average \$75 per ton. At the Surf Inlet mine some 250 men are employed, and the mine is turning out 450 tons, running about \$10 per ton, daily. An aerial tramway is to be built from the mine to the mill, a distance of about three-quarters of a mile.

Sheep Creek.—Harold Lakes, superintendent for the Nug-

10,000 piculs at 38.50 yen is reported as having been made for export to South China and of 5000 piculs at 39 yen to the Chinese government mint. The reduction in prices announced by foreign steel companies resulted in similar reductions by the Japanese government steel works. The price of cast-iron is announced as 170 yen per ton, a drop of 50 yen. In general the reduction announced April 18 amounts to approximately 20% on all stocks.

MANITOBA

The Pas.—A rich gold strike is reported at Elbow Lake, in the Athapapuskow mineral area. The vein is stated to be 50 ft. wide carrying free gold and has been stripped of its overburden for 350 ft. The find was made by the Murray brothers about three weeks ago and has caused great excitement.

MEXICO

Concepcion del Oro (Zacatecas).—Rodolfo Frias has applied for titles to four pertenencias bearing gold and silver, situated in this mining district.—The Mazapil Copper Co. is still operating its mines and smelter at Concepcion del

The Recent Fire at the Plant of the Utah Oil Refinery Co. at Salt Lake City

get Gold Mines, Ltd., complains that, notwithstanding the amount of unemployment said to exist in the Province, he is unable to get skilled miners. At the present time only 35 men are employed underground, and with that number he is entirely unable to maintain a supply of ore to keep the mill going. During May the mill crushed 2100 tons of ore, and made a considerable inroad on the supply of ore that had been broken in the stopes before the mill was started.

Vancouver.—The value of the Panama Canal to Canada, as well as to the United States, is being demonstrated in these days of high freight-rates. The 'Robert Dollar', which brought 700,000 lb. of steel cable for the Premier mine tramway, will carry back to New Jersey 2200 tons of blister-copper for refinement. This is said to be the largest single consignment that has ever gone East from the Anyox smelter.

JAPAN

Tokio.—The copper market is showing a remarkable improvement, both in reduction of stocks previously held and in price. The copper guild has for some time maintained the conventional price of 40 yen per picul (133½ lb.), but since February 1, actual sales have been ruling at from 35 to 37.50 yen. During the last week of the month orders have been placed at 39.70 yen for small lots. A sale of

Oro. There has been an improvement in freight-traffic, relieving the fuel-shortage.

Saltillo (Coahuila).—Francisco F. Salas, a mining man of this city, has located four claims in the Agujerada mountains valuable for their zinc ores. Development work is being carried on.

Sombrerete (Zacatecas).—Filings have been made at the mining agency in this city for titles to the following groups of mines: El Guardo, consisting of 12 pertenencias or mining claims, situated at La Noria; Santa Catarina, comprising 54 claims at San Miguel del Mezquital; Zuluaga, 4 claims at San Pedro de Ocampo; Purisima, 6 claims in La Noria district; La Gallega, at La Noria; La Soledad, comprising 11 claims near La Noria; and La Providencia group of 5 claims on the Hacienda de San Jose.

Torreón (Coahuila).—Construction work on the railroad from Rivas station to the Sierra de Ramirez mining region in the San Juan de Guadalupe district is being rushed to completion. The entire length of the line will be approximately ten miles, about seven of which is now completed. The branch will tap the rich mining district of the Ramirez mountains and will facilitate the transportation of ores from the numerous mines to the main line of the National Railways. It is one of the richest silver-lead districts of

the State of Durango. A number of new mines are being opened up in this vicinity which will be in condition to ship as soon as this new railroad is in operation. Contracts are being made with the Torreon smelter and the Aguascalientes plant. The latter has been operating only two copper furnaces, but will shortly blow-in one of its lead-furnaces.

ONTARIO

Cobalt.—Silver production from the mines of Cobalt has increased to between 750,000 and 800,000 oz. monthly. The four leading mines are in full operation, namely: the Nipissing, Mining Corporation, Coniagas, and O'Brien. Three other smaller mines are producing, these being the La Rose, Bailey, and Chambers-Ferland. Fire destroyed the transformer in the mill on the Keesley mine, and the mill will not be re-opened until the last week in June. Ore-reserves are now estimated to contain 600,000 oz. of silver. The Bailey custom mill treated 5019 tons of ore during May, 3960 tons being custom ore from the La Rose, Silver Leaf, and Ophir, and 1059 tons coming from the Bailey mine itself. Gross earnings on the custom ore treated amounted to \$11,838.

The annual meeting of the Ontario Mining Association was held at Cobalt on June 16, 17, and 18. In addition to the general invitation to those who represent the 41 Ontario mining companies which belong to the Association, special invitations were sent out to 36 individuals who are identified with the mining industry, five of these being officials of the Ontario Department of Mines. A feature of the meeting was a cruise on Lake Temiskaming and a visit to the Wright mine, where silver-lead ore was found more than a century ago and which is said to be the oldest mine in Canada.

Porcupine.—At the Dome mill the work of overhauling the stamp equipment, which has not been used for some years, has been completed, bringing the capacity of the mill up to about 1400 tons daily. The North Crown has been closed down, as explorations for the discovery of new ore were not successful. It is understood that re-financing will be necessary before work can be resumed. The Hollinger Consolidated is raising ore from the 1250-ft. level by the central and old Hollinger main shafts, which are down 850 ft., the lower level being reached by a winze.

SOUTH AFRICA

Johannesburg.—At the annual meeting of the Crown Mines, Samuel Evans, chairman, stated that the working profits for the year were £1,930,336, due mainly to the 'premium' on gold. The cost per ton mined was 51% higher than in 1914. He said that the chief problems confronting the industry were the supply of unskilled labor and working costs. Regarding the prospect for the future, the chairman said that the annual production of gold in the world had diminished by 27% since 1915, while the probabilities were that in the course of the next few years the demand for gold would be greater than it had been since the adoption of the gold standard by England. During and since the War, the desire for gold among the people of the Far East had been enhanced, and the use of it for currency purposes both there and in South America had increased. It was almost certain that Russia would eventually come back to gold without any paper money in circulation as Mexico did five years ago and as France did after the Revolution. The time could not be far distant when the areas which constituted the Austrian Empire and other countries whose paper currencies had become almost valueless would also be obliged to abandon paper for gold. Undoubtedly the capacity of Russia and the neighboring States for absorbing gold was enormous, and it was quite conceivable that in a not distant future the peasants of those countries would be exporting the products of field and forest at prices in gold lower than anything ever heard of before.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. B. Lakenan sails from Seattle to Juneau on July 2.

J. E. Steele, of Hayden, Arizona, is at St. Louis, Missouri.

W. A. Argall, of Thane, Alaska, is at Denver, Colorado.

Horace W. Edmondson is now at Eden Four Corners, Vermont.

K. F. Klein has moved from New York City to Alma, Park county, Colorado.

William Forstner is opening up a gold mine in Siskiyou county, California.

M. Albertson has moved from Shreveport, Louisiana, to St. Louis, Missouri.

Frank G. Stevens, of Toronto, is visiting the Rex mine, Northern Manitoba.

Hugh Rose, manager of the Santa Gertrudis, at Pachuca, Mexico, has gone to London.

F. E. Calkins has been examining mines in Mohave county, Arizona, during the past month.

J. H. Hottendorf, recently at Yreka, California, is now with the Superior Dredging Co., at Bridgeport, Oregon.

Lester S. Grant, Dean of the Faculty in the Colorado School of Mines, is at Sonora, in Tuolumne county, California.

Bruce Marquand, recently metallurgist with the Sunny-side Mining Co., at Silverton, Colorado, is now at Berkeley, California.

Arthur E. Eddy has opened offices in the Electric building, at Billings, Montana, the firm of Eddy & Welsh having been dissolved.

Charles A. Mitke, of Bisbee, Arizona, recently addressed the Boston section of the A. I. M. & M. E. on the subject of mine-fires.

John W. Moule has resigned from the position of assistant resident manager for the Burma Corporation, Ltd., and is now in England.

Wallace Savage has resigned from the position of assistant editor of 'Chemical and Metallurgical Engineering' to enter private practice.

L. P. Barrett, geologist with the Michigan Geological Survey, has been examining mining properties in the Eureka mining district, Nevada.

R. C. Moore, geologist of the U. S. Geological Survey at Salt Lake City, is spending a few weeks in examination of gas and oil prospects in Kane and Garfield counties, Utah.

H. H. Stout, superintendent of the Copper Queen smelter at Douglas, has resigned and gone to New York, where he will continue to be associated with the Phelps Dodge Corporation.

H. V. Burgard, secretary of the Mineral, Metal & By-Products Co., has returned to San Francisco after visiting a number of gold and complex ore mines in several districts of California.

Haral R. Layng has resigned the superintendency of the Holly and Bullwhacker mines of the Eureka Holly Mining Co., and is now in private practice in San Francisco as a metallurgical engineer.

G. C. Greene, formerly research metallurgist for the Nevada Consolidated Copper Co., at McGill, Nevada, has accepted a position as engineer for the Copper Canyon Mining Co., at Battle Mountain, Nevada.

Victor C. Svinonoff, a prominent petroleum engineer of the Baku oilfields, formerly of the University of Pittsburgh, has recently returned from Russia, having escaped from the Bolsheviks. His temporary address is 370 West 120th street, New York.

Eastern Metal Market

New York, June 15.

An entire absence of improvement features in nearly all the markets, except possibly tin, and an easing in values is reported in most of the metals.

Buying of copper is no better than a week ago, either for export or domestic consumption.

Tin has been bought more liberally than any of the other metals.

Lead has been reduced in price and buying is limited to small quantities.

The zinc market is still lifeless.

IRON AND STEEL

So pronounced is the stagnation that the trade has given up hope that anything can be done to break the accentuated summer dullness, according to 'The Iron Age'. The continued excess of consumption over production is digging into stocks in consuming hands and some expansion in demand is expected in the early fall. The quick deliveries asked on many new orders indicate that stock balances are not being well maintained. Except for a further slowing down of operations, the week has been devoid of developments. Gaging the percentage of active producing capacity is difficult. It is doubtful if, for the industry as a whole, output is above 25%. The estimate for the Pittsburgh region is around 20%.

Price changes have been unimportant. The recessions, as in wire products, sheets, chain and cast-iron pipe, brought no better demand. Bidding for export business, small but conspicuous by comparison with the orders making up domestic sales, brings out price weakness.

The extent of the depression in the British industry is emphasized by the May production data. The pig-iron output was 13,634 tons and that of steel 5574 tons, against 60,300 tons of pig-iron and 68,400 tons of steel in April and a monthly average in 1920 of 667,325 tons and 754,733 tons respectively.

COPPER

No improvement is discernible nor is there prospect of it in the immediate future unless the foreign situation becomes better or the present depression at home shows some alleviation. Nevertheless there is not much pessimism in the copper trade. A fair consumption is reported, the sales for May having been not less than 110,000,000 lb. Production is getting smaller all the time so the net result is regarded as statistically favorable. Most producers are adhering to regular quotations of 13.50c. delivered, for June-July or are not quoting at all while a few, particularly one or two, will shade this to 13.12½ to 13.25c., delivered, but the quantity of metal available at these levels is small. Any demand would wipe out these concessions and values at once. For the business that is offered, and under the conditions, we quote the market for electrolytic copper at 13.25c., delivered, or 13c., New York, for early delivery, with Lake copper nominally about the same.

TIN

The market has been quite irregular the past week and consequently not easy to appraise, due largely to the fluctuations in sterling. Nevertheless there has been a fair amount of buying by both dealers and consumers. It is estimated that for the week ended with Friday or Saturday about 600 to 800 tons changed hands, but on the surface the market was decidedly quiet and not indicative of any activity. Monday of this week, June 13, there was further buying at 28.75c. for futures, with 29c. asked at the close for Straits

tin. Yesterday the quotation for spot Straits was 29.25c., New York, against 29c. a week ago. The London market has varied during the week, but yesterday quotations were £1½ to £2 per ton above those a week ago, with spot standard at £167 10s., future standard at £169 10s., and spot Straits at £168 per ton. Arrivals thus far this month have been 787 tons; 3000 tons is reported afloat.

LEAD

Another reduction has been made by the American Smelting & Refining Co. from 4.75 to 4.50c., both New York and St. Louis. This was actually put into effect last Friday, June 10, but not generally known until late Monday, June 13. There is no improvement in demand and the market is stagnant and featureless. On the basis of the outside market as representing actual business the market may be quoted at 4.50c., New York, or 4.25c., St. Louis.

ZINC

The market for prime Western is absolutely stagnant and values are a little lower. Wholesale lots for early delivery are quoted at 4.45c., St. Louis, or 4.95c., New York, which is 10 points under a week ago. The brass interests are doing almost no buying though their business is fairly good, but they are still using large quantities of scrap brass and adding special zinc for which there has been a good demand lately. Galvanizers are decidedly inactive, due to the depression in the steel industry, but when they buy it is for prompt delivery which is testimony to the effect that stocks of metal are very low.

ANTIMONY

Wholesale lots for early delivery are unchanged at 5.20c., New York, duty paid, with demand very light. Jobbing lots are quoted at 5.30 to 5.50 cents.

ALUMINUM

There has been no change in demand or prices. The leading producer continues to quote virgin metal at 28c. f.o.b. plant, in wholesale lots for early delivery, while other sellers quote the same grade of foreign make at 22.50 to 23.50c., New York.

ORES

Tungsten: Buyers are uninterested and prices are largely nominal and unchanged. Chinese ore can be bought at about \$3.25 per unit with Bolivian and domestic higher grade ores at about \$4 to \$4.25 per unit.

Ferro-tungsten is quoted at 48 to 58c. per pound of contained tungsten in lump form, guaranteed quality.

Molybdenum: The market is inactive and nominal at 50c. per pound of MoS₂ in regular concentrate.

Manganese: There is no demand with stocks heavy and importation large. Quotations are nominal at 22.50c. per unit, seaboard, for high-grade ore.

Manganese-Iron Alloys: Demand is light for both ferro-manganese and spiegeleisen and quotations are unchanged. British ferro-manganese is quoted at \$75, seaboard, and the American alloy at \$80, delivered. Spiegeleisen is obtainable at \$30 to \$32, furnace. One consumer is asking bids on 500 tons and one lot of 100 tons was sold at close to the minimum figure.

Ferro-silicon, 50%, has sold at new low prices for recent years. It is stated that one seller has taken an order at \$74, delivered, against \$80 which recently ruled, while another seller will sell at \$69 to \$70 per ton, delivered, for early delivery.

EASTERN METAL MARKET

(By wire from New York)

June 20.—Copper is inactive and lower. Lead is dull but easy. Zinc is stagnant and unchanged.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

OIL IN SOUTH AMERICA

That Colombia will soon be one of the leading oil countries in South America is indicated in a report on the oil industry of that continent by J. W. Thompson, of the United States Bureau of Mines. He says that South American fields are admirably situated for distribution of petroleum by water to all nations using oil as fuel for shipping and industrial concerns.

According to the report, the International Petroleum Co., a Standard Oil subsidiary, is spending more than \$25,000,000 on development of the De Mares concession in the heart of Colombia, which it purchased from the Tropical Oil Co. This concession contains 1,300,000 acres and has three producing wells. A six-inch pipe-line has been laid to a refinery at Barranca Barrera. A railroad and a tractor road are being constructed. The company has also purchased an island at the mouth of the Magdalena river on which it plans a refinery, ultimately to have a capacity of 25,000 bbl. daily. It is also laying a pipe-line from De Mares concession, 300 miles up the river, to tide-water, at a probable cost of \$3,000,000.

Concessions have been obtained in Colombia by various interests and wells drilled farther up and lower down the Magdalena river and in large numbers along the coast about Gulf of Darien. From Honda, on the upper Magdalena, north and north-easterly some 650 miles to Lake Maracaibo, in Venezuela, there is now almost a continuous line of concessions.

Regarding the oil industry of Venezuela, the report says oil concessions and their development are confined principally to territory bordering Lake Maracaibo, and concessions have been granted for about 75% of the land immediately around the lake. British and American companies are active, and in 1920 eight wells were completed at an average depth of 1200 ft., producing a total of about 6000 bbl. daily. Four wells of the Colon Development Co., owned by the Royal Dutch-Shell-Carib Syndicate interests, have a daily capacity of about 4000 barrels.

Argentine production is running more than 25,000 bbl. per week, according to an official estimate. There is a disposition to grant private interests the right of participation in development of Argentine fields, and British and American interests are active. Big concessions have been granted in Bolivia, without any guaranty of early development. There are several districts in Brazil where oil indications are promising, and Brazilians or foreigners residing in Brazil may operate under license granted upon application. There have been no important oil discoveries in Chile so far as known, although surface manifestations have been found. Exploitation is permitted under license. A change in petroleum laws of Ecuador is regarded as indispensable for encouragement of the oil industry. Nevertheless, a British company is endeavoring to acquire rights over 60,000 acres on Santa Helena peninsula. Peru is one of the pioneer countries in oil development of South America. In 1913 production was 2,671,000 bbl. At the beginning of 1920 the annual production was estimated at 2,500,000 bbl. A large amount of refined products is exported from Peru, there being a substantial refining industry. An exportation tax of one shilling per metric ton is imposed on petroleum and its products.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE 'ROLLSRIGHT' CAR TIPPLE

By A. G. Reese

Various types of rotating car tipples are used for dumping mine-cars, the source of power being compressed air, steam, or electricity. Rotary car-tipples have many advantages over the end-dump type, as cars without dump-bottom or end-gates can be used. This feature eliminates largely any scattering of material along the haulageways which is characteristic of any other type of car, and also

the top of the slope the cars enter either of the two 'Rollsright' car tipples which are placed over a 300-ton pyramidal bin. The average capacity of this mine is 1500 tons in 8 hours. At No. 3 Dolomite mine are situated two five-car 'Rollsright' tipples. The cars at this mine are brought to the face of the slope by electric locomotive and there made up in trains of five, which are hauled up a 30° slope 1400 ft. long at a speed of 2000 ft. per minute by a 700-hp. double-drum electric hoist. The 'Rollsright' tipples are set at an angle of 15° over a 400-ton double bottom V-shaped bin. The cars at both the Dolomite mines are dumped without detaching from the hoist-rope. Both of the above described tipples are used for coal, the weight of each loaded car being 4600 pounds.

For the installations described above swivel car-couplings are not used, as the entire train is dumped at one operation. The 'Rollsright' tipple can be applied also to conditions where it is desired to dump a number of cars without detaching them from the remaining train.

The general description of the 'Rollsright' is as follows: The tipple will dump one or any number of cars at one time and will make a complete dumping cycle in five to seven seconds.

It is controlled entirely by one latch-lever which holds the tipple in upright position. The centre of gravity of the loaded car or cars is 'off centre' of the tipple sufficiently that when released

by latch-lever the tipple rotates through an arc of about 135°, setting in motion a set of flywheels situated on the roller shafts. At the end of the 135° arc the tipple ring engages with a specially designed spring and wedge, which stops the forward motion of the tipple. The centre of gravity of the car or cars is now on the opposite side of the centre line of tipple. This feature in connection with the recoil action of the springs starts the tipple in the opposite direction and brings the flywheels up to speed, their momentum carrying the tipple around to its original position where it automatically latches. All the rollers which support the tipple are carried on shafts mounted in Hyatt roller bearings which reduce friction to a minimum.

AN ANNIVERSARY

On June 25 the Robins Conveying Belt Co. celebrated its twenty-fifth anniversary. The organization was founded on June 25, 1896, to develop an idea—the handling of material by means of the belt-conveyor. Twenty-five years ago

'Rollsright' Car-Tipple

eliminates the trouble due to accidental opening of doors when cars are traveling at high speed.

Solid type cars are lighter, cost less for repairs, are more rigid, have longer life, and lower initial cost. The Wellman-Seaver-Morgan Co. has placed on the market an entirely different type of rotating tipple in that it does not require any power for operation except that furnished by the car itself; this results in many advantages principally as follows: simplicity of construction, the result of which is lower first cost; simplicity of operation which allows the employment of unskilled labor; lower maintenance charges; and increased production.

There are now several of these tipples in operation, the first one being at a coal-mine adit known as Dolomite No. 1 of the Woodward Iron Co., at Birmingham, Alabama. The coal-cars, after being brought to the foot of the slope by an endless rope, are attached in sets of four to the tail-rope and hoisted at a speed of 1500 ft. per minute up a double-track slope 1900 ft. long having a maximum grade of 26°. At

industrial quantities were small. The largest conveyor then in existence, made of chain and steel plate, carried 200 tons per hour. The belt-conveyor—then a new thing—was laughed at by many engineers who refused to believe that rubber excelled steel in resisting abrasion, but when this was found to be so, and the belt-conveyor was demonstrated to be a durable and economical device of enormous capacity, engineers quickly adopted it, and a tenfold increase in industrial quantities has been very largely due to its employment. The engineer of today can handle two or three thousand tons per hour more easily than one-tenth of such quantities was formerly moved.

In a thousand industries the belt-conveyor is an efficient link between processes. Formerly it was necessary to fit conveyors into existing plants, but today the handling of material is such a controlling element that the requirements of the conveying system usually determine the situation and arrangement of the buildings. Pioneers in the handling of large quantities, the Robins company has developed many systems and devices for the treatment and storage of materials. These include car-dumpers, unloading-towers, storage-bridges, self-unloading vessels, and steel structures of all kinds. The company also manufactures large and small castings, gearing, screens, and power-transmission machinery.

COMMERCIAL PARAGRAPHS

The Denver Quartz Mill & Crusher Co., of Denver, is shipping a carload of machinery including a No. 2 Denver quartz mill to the McCue brothers, Dutch Guiana, where it will be used in the milling of gold ore.

Allis-Chalmers Manufacturing Co. has issued Bulletin No. 1117, entitled 'Small Generating Sets'. These are particularly well suited for isolated lighting and power-plants where steam is available as the prime source of power.

Bulletin No. 5, entitled 'Victor Damper Regulator, No. 3, High Pressure', has been issued by the Atlas Valve Co. This regulator is designed for boiler pressures up to 250 lb. The damper control-cylinder is operated in both directions by water-pressure admitted through a pilot-valve. The compensating attachment limits the travel of the control cylinder on intermediate pressure changes and permits the regulator to fully open or close the damper only on extreme pressure variations.

The Chicago office of the Uehling Instrument Co. of New York, manufacturer of fuel-saving equipment, was moved May 1 to the Great Northern building, 20 West Jackson boulevard. Walter C. Lange, who has been appointed manager of this office, is well qualified to co-operate with power-plant operators in solving problems of fuel conservation because of his former experience in this field. Uehling 'CO₂' recording equipment and other boiler-room instruments will be on display in the new office.

Curtis steam turbines of 100-kw. to 3500-kw. capacity have been developed for driving 60-cycle generators at 3600 r.p.m., according to Bulletin No. 42201-B, issued by the General Electric Co. These units are adapted for industrial and lighting plants requiring economical and reliable generation of electric power. As no internal lubrication is necessary, and as the oil is circulated through the bearings in a closed system, the cost of oil is small. The cost of attendance is also small, and, on account of the simple and strong construction, the cost of repairs is low. Under maximum working conditions, steam may be extracted from a Curtis turbine for heating and manufacturing purposes. The steam, which passes through all stages of the turbine to the condenser, is used at the same high efficiency as in a turbine from which no steam is extracted.

The Hauck Manufacturing Co., of Brooklyn, manufacturers of oil-burners, oil-forges, oil-burning appliances, etc.,

has elected as its president, Henry T. Gerdes, mechanical engineer and manufacturer of New York; first vice-president, M. C. Hauck; second vice-president, A. B. Hauck; third vice-president, H. H. Kress; treasurer, A. H. Stein; secretary, J. Lutz. H. T. Gerdes, who succeeds the late Arthur E. Hauck, is well fitted for his new position. He is a graduate of Stevens Institute of Technology. He has a practical knowledge of the manufacture of oil-burning torches and appliances.

In addition to reducing its prices, on June 1, the Hercules Powder Co. announced that it had developed formulae—the result of exhaustive studies and experiments—which have enabled it to discontinue the manufacture of high-freezing dynamites without sacrificing any desirable features which those grades possessed. This means that Hercules 'Extra' and 'Gelatin' dynamites, 'Hercules Special No. 1', and 'Hercomite', and most of the 'Straight Nitroglycerin' dynamites and 'Red H' permissible explosives can now be used without thawing under all temperature conditions that are found in practically any blasting work.

The Pawling & Harnischfeger Co., of Milwaukee, has designed and improved a safety cage for traveling cranes. Space is always at a premium in crane-cabs, and for this reason exposed knife-switches, magnetic-control parts, and resistors introduce a serious hazard. In previous P & H crane-cages a false bottom in the cab was provided for the resistors, greatly simplifying the upper part, but now by providing front-lever control and placing the entire controller equipment and current-carrying parts in an enclosure, a maximum of safety is provided. The levers which operate radially (backward and forward) are placed at the front of the cage and afford the operator an entirely unobstructed view. He can see the position and movement of the crane-hook, the signals of floor-men, and the entire floor as the crane travels along the runway. Crane operators prefer the radial motion of control-levers to the 'coffee-mill' movement previously employed. The crane operator can by no chance come in contact with live parts, even the main knife-switch is operated from the exterior of the cabinet. Opening the hinged doors exposes all parts for inspection and adjustment. The rear-of-board wiring is accessible by removal of an enclosing panel at the rear. This new cage has been in actual operation on a number of cranes and performance watched for the past year before standardizing.

The General Electric Co. has standardized a complete line of 60-cycle synchronous condensers, for power-factor control, to meet the demand for a comparatively inexpensive high-speed machine. These condensers are described in Bulletin No. 41311-A, superseding Bulletin No. 41311, entitled 'Synchronous Condensers'. These machines are of light mechanical construction and possess other features which permit a reduction in the amount of material required and a consequent lower cost, without lessening their value as synchronous condensers. The standard machines are designed for operation on 480, 600, and 2300 volts in the smaller sizes; 2300 volts in the intermediate sizes, and 6600 and 13,200 volts in the larger sizes. Several advantages of making the synchronous condenser an integral part of a power-system, for power-factor control, are cited by the bulletin. These involve the total cost of the equipment required to handle a given load, the regulation of long high-voltage transmission lines, additional load which can be carried, and the increased operating efficiency which is possible. The bulletin also describes the use of automatic starting and control equipment for synchronous condensers in cases where it is not always possible to have attendants; and the use of these machines to drive a mechanical load. Calculations necessary in figuring on a synchronous condenser installation, a wiring diagram, and other data are included in the bulletin.
